The spiral spring is coiled up into a box, which is marked A in the Figure, and is fastened to the frame. The interior end of the spiral spring is connected with the main arbor B, which is supported by the plates R, S. On this arbor the wheel C with its ratchet-wheel Z is fixed, and turns the small pinion D on the second arbor E; at the end of this arbor, the contrate or escape-wheel F is fixed; and G is a vertical arbor with two pallets *a* and *b* projecting from it, the one engaging in the teeth on the upper side of the contrate-wheel, and when the pallet *a* is not in action, the pallet *b* intercepts the lower teeth of the wheel. This is a crown-wheel escapement, such as is used in common watches, and gives motion to the arbor G alternately in a backwards and forwards direction. On the lower end of the arbor G a sector C is fixed, and is cut into teeth at its circumference, to form a segment or portion of a wheel. It gives motion to the pinion H on the short vertical arbor *d*; and the wheel I is fixed on the same arbor, to give mo-

Spring jack. PLATE CCXCIX. Fig. 4.

tion to the pinion L, in the centre of the jack, which is fixed on the vertical arbor *m*, that passes through the bottom plate of the bottle, and has the fly-wheel O fixed to it, with the hook P for suspending the meat. The arms of the sector *c* are sufficiently extended to admit the arbor *m* between them. The arbor is sustained by the fixed cock *i*, and is also suspended by a number of small catgut strings going up through the centre of the jack to the top of the neck of the bottle, and attached to the cross pin *r*. These strings take off part of the weight of the meat which is suspended on the hook P, and diminish the friction on its collar. This effect is also partly produced by a small spiral wire spring *t* coiled round the arbor, and bearing on the cock *i*.

The spring jack is wound up by the key Q, when applied to the square part *s* of the main arbor; and in the act of winding, the great wheel C is not turned round by the ratchet wheel *z*, because the click fixed to the great wheel slips over the sloping side of the teeth. To prevent the spring from breaking, a pinion *n* is fixed on the end of the main arbor; beyond the plate it works into the wheel *o*, which turns upon a pin fixed into the side plate S of the frame. When the main arbor has made a sufficient number of revolutions to wind up the spring, the leaves of the pinion *n* come in contact with a part of the wheel *o*, which has no space in it, and this prevents the arbor being turned any further, so as to endanger the breaking of the spring. The maintaining power of the spring, when wound up, gives motion, by the wheel C and pinion E, to the escape wheel F, the upper tooth of which meets with the pallet *a*, and carries it along with it, turning the vertical arbor round upon its pivots. This motion is communicated by means of the sector C to the pinion H, and its wheel I, and thence to the sector pinion L, and the fly wheel, and consequently to the meat. The use of the wheel-work CHL is to make the meat turn round several times before the tooth of the wheel escapes the pallet *a*, and then the tooth on the underside of the escape wheel meets with the pallet *b*, and turns the vertical arbor G, and the fly wheel back again, in a contrary direction to that in which it was before turned by the pallet *a*, because the underside of the escapement wheel is going in a contrary direction to the upper side; when the under tooth of the wheel escapes from pallet *b*, the pallet *a* comes into action again, and thus a continuous motion is kept up, first in one direction for a few turns, then in the opposite direction, and so on, till the maintaining power of the spring becomes exhausted, when it must be wound up again by the key Q. The tube resembling the neck of the bottle is to give length to the catgut strings before mentioned, and which, by their twisting and untwisting, perform nearly the same office as the pendulum spring in a watch, and make the fly wheel return back readily. The bottom V of the bottle is screwed to a flaunch or projecting rim round the bottom of the bottle, by removing these screws, and taking out the cross pin *r* in the top of the neck which hold the strings; the frame containing the wheelwork may be withdrawn from the case *x x* to be repaired or oiled as occasion may require. (J. F.)

JACKSON, PORT. See BOTANY BAY and *New* HOLLAND.

JAEN is a town of Spain, and the capital of the ancient province of the same name, which is now under the government of Andalusia. Jaen is supposed by some to be the *Oningi* of Pliny, the *Oringi* of Livy, and the *Mentessa* of the Romans. The city, which is situated at the foot of a mountain of mixed marble, is surrounded by walls flanked with towers. The town is of a middle size, and has some squares, one of which is spacious. The water, with which the town is well supplied, is distributed in the squares, streets, and houses. Jaen is the see of a bishop, suffragan of the archbishop of Toledo, formerly fixed at Bäeza. The diocese contains two cathedral chapters, one at Bäeza, and the other at Jaen; two collegiate chapters, one at Bäeza, and the other at Ubeda; seven archpriests, and 438 parish churches. The principal public buildings are the cathedral and parish churches, and a great number of monasteries, nunneries, and two hospitals. The cathedral is a noble piece of architecture. The eastern front, flanked with two fine towers, is adorned with eight Corinthian columns, and has three doors embellished with bas reliefs. The chapel of the Sacrario is esteemed a fine piece of architecture. The parish church of St Claire contains an exquisite painting of the Virgin and our Saviour. The convent church of the nuns of St Claire is a handsome building, and the principal altar is adorned with some excellent paintings by Angel Nardi. Jaen was formerly a rich and commercial town, but its silk manufactories failed about the end of the 16th century. About the middle of the 18th century, 5000 tape looms, 1200 ribbon looms, and several silk ones, were set to work, but they did not succeed, and few of them remain at present. The country around Jaen is rich and beautiful; the silk-worm is reared, but not in great quantities. Population 30,000. See Laborde's *View of Spain*, vol. ii. p. 117.

JAFFA, is a seaport town of Palestine, situated upon the declivity of a hill on the eastern shore of the Mediterranean. It has a good wharf, but the harbour, which seems to have been of considerable size formerly, is now small, and is only frequented by coasting vessels making the voyage to Syria. By clearing it out, it has been conceived capable of receiving 20 vessels of 300 tons, such as are now obliged to anchor in the roads, where they are always ready to slip their cables, from the frequency of sudden storms. On all the coast of Syria there is scarcely a safe harbour. The declivity upon which the town of Jaffa stands, is so unequal, that the streets are paved in steps. The whole is surrounded by walls, fortified with tolerable regularity, and capable of defence, though commanded by a height. On the southern side, it has one large bastion, with several towers crowned with artillery, which flank the line of walls; but these are said not to be of sufficient strength. There were recently two principal gates, and a third of a smaller size; but one of the former was shut up. The houses are neatly built of stone; and being distributed on the declivity, rise above each other like the seats of an amphitheatre, and there is a tower or citadel on the summit. There are three small convents here of Christians, Greeks, and Roman Catholics, whose numbers are probably much smaller since pilgrimages to the Holy Land have become less frequent. In 1807, there were but four Roman Catholics in their monastery, and they were all Spaniards. Only a few Jews are in the town, the population consisting of a mixed race, among whom is a numerous garrison of Turkish and Maugrabin soldiers; the total amounting to about 6000 or 7000. Water is scarce in Jaffa, notwithstanding the vicinity of a small river: It may be obtained, however, by digging for it on the coast;

and it is said, that one of its governors who engaged to remedy this inconvenience, was strangled by order of Djezzar, Pacha of Acre. The climate seems to have a tendency to insalubrity, which has been attempted to be corrected by draining extensive marshes. Soap is the principal manufacture of this town, as it is of several considerable towns of Syria, from all of which it is sold under the name of Joppa soap, and is exported for supplying Egypt. Oil of olives was one of its chief ingredients; but the groves of olive trees which covered the neighbouring country, and also those of oranges, lemons, and other fruits which adorned the town, were destroyed by the Mamelukes during the sieges of Ali Bey and his successor. Spun cotton is exported in small boats to Acre, whence it is shipped for other places, and also the provisions, the produce of the country. Jaffa is governed by an officer, who is said to be appointed by the Kislar-Aga or chief of the Black Eunuchs in the Turkish emperor's service, but the regulations under which the military subsist are not explained. The governor pays a small tribute to the Porte, which he levies in customs from merchandize and taxes on the town and villages dependant on him: his authority seems to have been very low about thirty years ago, but events more recent have rendered Jaffa of greater importance. The town subsists by its commerce, and the resort of pilgrims to the Holy Land, who find a reception in some of the monasteries: part of the money paid by them for this privilege, however, is diverted into a different channel. Jaffa is celebrated as the Joppa of Scripture: the spot where the Roman Catholic monastery stands is said to have the site of the house of Simon the tanner: and on a rising ground, about a mile east of the town, are some ruins, called those of the house of Tabitha, who was raised from the dead by St Peter, and where Pococke supposes there was a church dedicated to her, as the Greeks resort hither to perform their religious rites on the day of her festival. In profane history it is equally celebrated; for here Perseus is believed to have rescued Andromeda from danger; and Jerome affirms that in his time the rock to which she had been bound was still pointed out. Jaffa was destroyed by the Sultan Saladin in 1191, after which it was rebuilt and fortified by the Christians.

During the arduous contest which subsisted for so many years among the principal European powers towards the close of the eighteenth century, a French army invaded Egypt. A force of 12,428 men commanded by Bonaparte was detached to act against Syria in February 1799, principally, it is said, with the view of reducing Acre, in retaliation for the capture of the fort of El Arisch by Djezzar. This army succeeded in taking every place on the route with facility, and at length reached the walls of Jaffa on the 7th of March of the same year. With regard to the consequences of the ensuing siege, the keenest controversies have been agitated by our contemporaries: on the one hand it has been said, that the French exercised unheard of enormities on the captured garrison: on the other, these have been as strenuously denied.

The Turks believing themselves invincible behind their walls, cut off the head of a messenger who carried a summons from Bonaparte to surrender, and did not answer it. But the French batteries being completed in three days, the fire of twelve-pounders opened at seven in the morning of the 7th, the summons having been sent at day-break, and was directed against a kind of square tower where the wall seemed weakest, on the south-west of the town. The breach appearing practicable by three o'clock, the signal was given for storming, amidst a fire well sustained by the garrison. The French advanced boldly; but no sooner had they penetrated the streets, than they gave themselves up to the fury sanctioned by an assault, massacring who ever ventured to oppose them. "All the horrors which accompany a storm are seen in every street, and repeated in every house. Here are heard the screams of some youthful female, the victim of violation, vainly imploring succour from her outraged mother, or calling on the name of her father, who is mercilessly murdered. No asylum is respected: streams of blood are flowing: and at each footstep appears a being groaning in the agonies of death." General Berthier ordered an officer M. Miot, to take a detachment, and carry the wounded off the breach; on arriving at the spot, he found that his whole detachment had forsaken him. Thus disappointed, he entered the city. "What a spectacle," he exclaims, "was there! the pallid hue of the inhabitants; their terror; the shouts of the soldiers; women wandering about despoiled of their veils, recognizing their dead or dying relatives among the disfigured bodies. The ground was overspread with dresses and furniture, and the soldiers selecting the richest from among the pestiferous garments." While all this was going on, a considerable portion of the garrison had retired into one of the forts, where they laid down their arms, and were conducted to bivouac before the tents of the general's staff. The Egyptians were selected from among them, and removed; and the remainder, consisting of between 2000 and 3000, Sir Robert Wilson seems specifically to affirm 3800, Turkish artillerymen, Maugrabins and Arnauts, were put under the guard of a strong detachment. Next day they were sparingly supplied with biscuit, and parties of them were carried to get water in some vessels with which they had been furnished.

Meantime Bonaparte, elated with his conquest, issued proclamations to the inhabitants of the various towns of Palestine, giving them an option of peace or war, declaring that he was merciful to the troops surrendering at discretion, but those were treated with severity who had infringed the rights of war. He also solicited the friendship of Djezzar, and his hostility towards the Mamelukes and the English.

It does not appear how these overtures were received, or what time was allowed for an answer; but on the 10th of March, a little after mid-day, the prisoners of Jaffa were put in motion, surrounded by a vast square battalion formed by the French divison of General Bon. Suspicions arising in the French army regarding their disposal, induced many not appointed for that duty to accompany the columns of Turks, who marched in profound silence. At length, having reached the sandy downs, about a mile south-west of Jaffa, they were halted near a marsh containing turbid water, when the commanding officer of the French directed that the whole should be partitioned into small groups. The order being accomplished, the victims were conducted to different points, and inhumanly butchered in cold blood: an atrocity unexampled in the modern history of civilized nations. Notwithstanding the number of troops employed in it, the execution of this horrible sacrifice required a long time, and it is affirmed that it was only with extreme repugnance that the soldiers fulfilled the duty imposed upon them. All the prisoners suffered with the most heroic fortitude, with the exception of a single youth, who made a fruitless appeal to the humanity of his merciless conquerors. Those who could accomplish it, with uncommon resignation performed that ablution which their religion enjoins, by means of the stagnant water, and then bid each other adieu; but none ever attempted to escape. In narrating these events, M. Miot observes, "I saw a respectable looking old man, whose manner and appearance denoted superior rank, I saw him coolly cause a hole be dug in the sand at his feet, deep enough to admit of his being buried alive.—Doubtless, he wished to perish by his own hands. He stretched himself on his back in this melancholy tomb, which now afforded him protection, while his comrades, offering supplicatory prayers to heaven, soon covered him up with sand. Then they stamped on the earth thus enshrouding him, as if to give a more speedy termination to his sufferings. This spectacle made my heart palpitate within me. It took place while the groups scattered on the downs were massacred. At last, of all the prisoners none remained but those who were beside the marsh. The cartridges of our soldiers were now expended; and it was necessary to dispatch them with swords and bayonets. I could no longer support this horrible butchery. I fled from it pale and ready to sink; but several officers told me in the evening, that some of those miserable beings, yielding to that irresistible impulse which prompts mankind to avoid destruction, leapt on each other, and thus received in their limbs the blow which was aimed at their hearts. If the truth must be disclosed, a frightful pyramid was reared of the dead and dying, streaming with blood; and it became necessary to remove those who had expired, in order to murder others who, sheltered by this terrific rampart, had not yet been struck." Their bones are said to have lain long in heaps, and to have been shewn to travellers; but Dr Clarke could not find any traces of them, nor even obtain the most distant information that such a massacre had ever taken place.

In regard to the inducements which led to an event so noted in the history of Jaffa, the French affirm, that these were unconnected with the thirst of revenge, or the love of cruelty. Their army, already reduced by the sieges of El Arisch and this unfortunate town, daily became still more enfeebled by the ravages of disease. Great difficulty of subsistence was experienced, and the soldier rarely received his ration complete. The scarcity was increased by the hostile disposition of the inhabitants of Syria and Palestine towards the French. "To maintain the prisoners," they pleaded, "by keeping them along with us, was not only augmenting our necessities, but would have been a constant restraint on our motions. Confining them in Jaffa was admitting the possibility of revolt, considering the slender guard that could be left to watch them, without removing the former inconvenience. Sending them back to Egypt would have required a considerable detachment, and reduced our troops greatly. To liberate them on their parole was, notwithstanding all engagements, hazarding an addition to the number of our enemies, and particularly to the garrison of Acre. Thus there remained only one universal measure of conciliation; it was frightful, but it was judged the result of necessity."

The exact number of the Turkish garrison thus massacred by the French is not exactly ascertained. Sir Robert Wilson states it at 3800: M. Miot, a spectator of the victims, thinks there were not quite so many. But possibly Bonaparte's manifesto to the Egyptians may be considered an ingredient of evidence, wherein he says, "he found at Jaffa about 5000 of the troops of Djezzar. He destroyed them all; very few saved themselves by flight." Such is a brief account of this memorable tragedy, the truth of which has been so keenly controverted in Europe.

The French have been charged with another atrocity in poisoning 580 of their own sick and wounded in the hospitals at Jaffa; but happily it has not yet received the same confirmation we believe as the former. In their retreat from Acre in May 1799, they seized on all the stores found in Jaffa, and blew up the fortifications, which have since been repaired. Distance from Acre 40 miles South. Lat. 32° 2′ N. Long. 34° 58′ E.

JAMAICA.

Situation and extent.

JAMAICA, the most considerable as well as by far the most valuable of the British West India islands, is situated in the Atlantic Ocean, among what are called by geographers the Greater Antilles, in 18° 12′ of North Latitude, and 76° 45′ West Longitude from London. The latitude of Kingston, the principal town, is 18° north; the latitude of Morant point east is 17° 56′, and its longitude 76° 6′; and the latitude of South Negril Point west is 18° 16′, and its longitude 78° 32′. Jamaica is nearly of an oval form; 140 English miles in length, and in its broadest part about 50. It is the third in size of the islands of the Archipelago. It is bounded on the east by the island of St Domingo, from which it is separated by the channel called by English seamen the Windward passage: by Cuba on the north; by the Bay of Honduras on the west, and by Carthagena in New Spain on the south.

Divisions and principal towns.

Jamaica is divided into three counties; Middlesex, Surry, and Cornwall. The county of Middlesex is divided into eight parishes, which contain one town and thirteen villages. The town is called St Jago de la Vega, or Spanish Town; and as this is the residence of the governor, it is accounted the capital of the island. The county of Surry contains seven parishes, in which there are two towns and ten villages. The chief of these is the town and parish of Kingston. Port Royal is also in this county, and likewise the villages of Port Morant and Morant Bay, the latter of which is a place of considerable importance, on account of its shipping. The parish of Portland in this county contains the vilage of Port Antonio, the harbour of which is one of the most commodious and secure in the island. The parish of St George contains Annotto Bay, a shipping place. The county of Cornwall contains five parishes, in which are situated two towns and eight villages. The towns are Savannah le Mar, which being destroyed by the hurricane in 1780, consists at present only of 60 or 70 houses; and Montego Bay Town on the north coast. The villages of Jamaica are generally small hamlets on the bays, where the produce is shipped in the *droggers*, to be conveyed to the ports of clearance. The few other places worthy of mention are Falmouth on the north coast, on the south side of Martha Brea harbour; Lucca harbour, also on the north coast; Bluefield Bay on the south coast, three leagues east of Savannah le Mar, the usual rendezvous of the homeward bound fleets; and Carlisle Bay, also on the south coast. The chief headlands of the island are Point Morant, more generally known to seamen by the name of the East End of Jamaica, and dreaded by them for its thunder and lightning squalls. Nepil by North and Nepil by South are two promontories on the west end of the island. The islands deserving mention near Jamaica, are the Pedea Keys and Portland Rock, on a large bank south of the island, and Morant Keys, eight leagues south-east of Morant Point.

Mountains and face of the country. The island is crossed longitudinally by an elevated ridge, called the Blue Mountains. What is called the Blue Mountain Peak, rises 7431 feet above the level of the sea. The precipices are interspersed with beautiful savannahs, and are clothed with vast forests of mahogany, lignum vitæ, iron wood, logwood, brazilletto, &c. On the north of the island, at a small distance from the sea, the land rises in small round topped hills, which are covered with spontaneous groves of pimento. Under the shade of these is a beautiful and rich turf. This side of the island is also well watered, every valley having its rivulet, many of which tumble from overhanging cliffs into the sea. The back ground in this prospect, consisting of a vast amphitheatre of forests, melting gradually into the distant Blue Mountains, is very striking. On the south coast the face of the country is different; it is more sublime, but not so pleasing. The mountains here approach the sea in immense ridges; but there are even here cultivated spots on the sides of the hills, and in many parts vast savannahs, covered with sugar canes, stretching from the sea to the foot of the mountains, relieve and soften the savage grandeur of the prospect.

Soils. The soil of Jamaica is, in many places, deep and fertile. On the north side, chiefly in the parish of Trelawney, there is a particular kind of soil of a red colour, the shades of it varying from a deep chocolate to a rich scarlet. In some places, it approaches a bright yellow; but it is every where remarkable, when first turned up, for a glossy shining surface; and for staining the finger like paint, when it is wetted. It seems to be a chalky marl, evidently containing a large portion of calcareous matter, from the circumstance of its holding water, when formed into ponds, like the stiffest clay. What is called the *brick mould* in Jamaica, is a deep, warm, mellow, hazle mould, with an under stratum so retentive, as to retain a considerable degree of moisture even in the driest season. This is the best soil in the West India islands for sugar canes, next to the ashy loam of St Christophers, and is followed by the deep black mould of Barbadoes. On the whole, however, the cultivated soil of Jamaica is not remarkably fertile.

Rivers. The island has upwards of one hundred rivers, rising in the mountains, and running with great rapidity to the sea on both sides. This rapidity, as well as the obstructions from rocks, renders them unnavigable except by canoes. The deepest is the Black River on the south coast, which flows gently through a considerable tract of level country, and is navigable by flat boats for 30 miles. There are some medicinal springs, warm, sulphureous, and chalybeate. The most remarkable of these is in the eastern parish of St Thomas, in the neighbourhood of which, a village called Bath has been built. The heat of this spring raises the thermometer to 123 degrees. It is said that the Spanish settlers once wrought mines both of copper and silver; and one of lead was opened a short time since in the parish of St Andrew, but it was soon abandoned.

Climate. The climate of Jamaica, even on the coast, is temperate, the medium heat at Kingston, throughout the year, being 80, and the least 70. In ascending towards the mountains, the temperature quickly alters with the elevation; eight miles from Kingston, the maximum is only 70; at the distance of 14 miles from this town, where the elevation is 4200 feet, the average range of the thermometer is from 55 to 65, and the minimum in winter 44. On the summit of Blue Mountain Peak, 7431 feet above the sea, the range in the summer is from 47 at sun-rise to 58 at noon; and the minimum in winter is 42. The year may be divided into four seasons; the first commencing with the vernal or moderate rains in April or May, which usually last six weeks; the second season includes June, July, and August, and is hot and dry; the third includes September, October, and November, or the hurricane and rainy months; and the fourth December, January, February, and March, which are the most serene and the coolest months.

Vegetables and fruits. Besides the staple exports of Jamaica, consisting of sugar, indigo, coffee, and cotton; the cultivated vegetables are maize, Guinea corn, and calavances for the food of the negroes, and almost all the kitchen vegetables of Europe, besides many indigenous ones, as the sweet potatoe, yam, eddar root, callaloo, a kind of spinach, and the commonest substitute for greens, cassara, okasy, &c. Few of the northern European fruits thrive, but the indigenous ones are numerous and delicious; the principal are the plantain cocoa-nut, guava, sour-sop, sweet-sop, papaw, custard apple, cashew apple, granidella, prickly pear, pine apple, &c. The orange, lime, lemon, mango, and grape, have been naturalized, as well as the cinnamon tree, of which there are now considerable plantations. The bread-fruit tree, with other useful plants, has been introduced by the exertions of Sir Joseph Banks. This island abounds in various grasses of an excellent quality. **Grasses.** Of the native grass, good hay is made, but in no great quantity; but there are two exotic grasses that are extremely valuable, and yield an abundance of food for cattle; the first is an aquatic plant called Scots grass, from a single acre of which five horses may be maintained for a whole year. The seed of the other kind, called Guinea grass, was introduced into the island, about 70 years ago, as food for some birds brought from the coast of Guinea. Cattle are remarkably fond of this grass, and thrive wonderfully upon it. The greater part of the grazing and breeding pens throughout the island are supported chiefly by means of this invaluable herbage. **Forest trees.** The principal forest trees have been already mentioned; many of them rise to a prodigious height, as the papaw and the palmeto royal, the latter of which is frequently found 140 feet high; the trunks of the ceiba, or wild cotton tree, and the fig-tree also, often measure 90 feet from the base to the limbs; the former, when hollowed out, has been known to form a boat capable of holding one hundred persons. Of softer kinds of wood for boards and shingles, there is a great variety of species; and there are many well adapted for cabinet work, such as the breadnut, the wild lemon, &c. In mentioning the vegetable productions of this island, the wild pine ought not to be omitted; it is a plant that commonly takes root in the great forks of the branches of the wild cotton tree; by the conformation of its leaves it catches and retains the rain-water, each leaf resembling a spout, and forming at its base a natural reservoir, which will hold about a quart of water.

Wild pines.

Animals.

When Jamaica was discovered, it contained eight species of quadrupeds, the agouti, the pecare, the armadillo, the opossum, the racoon, the musk-rat, the alco, and the monkey. Of these only the agouti and the monkey remain. There are many varieties of the lizard, some of them very beautiful. The most delicious of the wild fowl are the ring-dove, and the rice-bird of South Carolina; the latter, after fattening upon the rice plantations in that district, visit Jamaica in prodigious numbers in October, to feed on the seeds of the Guinea grass. Parrots are still found in the groves, but the flamingo is no longer to be seen.

Few cattle are bred here, the asses and mules being imported from the Spanish Main, and the horses from England and America; the latter are in general excellent, and sell at from £100 to £140 currency. The black cattle are of a large size. There are also asses and sheep; the mutton is well tasted, but the wool is hairy and coarse. There are likewise goats and hogs in great plenty; sea and river fish; wild, tame, and water fowl. Near the coast there are salt ponds, from which formerly the inhabitants supplied their own consumption.

Commercial productions.

The commercial productions of the island are sugar, rum, molasses, coffee, cocoa, cotton, indigo, pimento, and ginger.

In the year 1673, the chief productions of Jamaica were cocoa, indigo, and hides. The cultivation of sugar had just commenced. It appears from the following statement, that the increase in the growth of this staple article of the island has been very gradual.

In the year 1722	. .	11,000 hhds. were exported.
1739	. .	33,155
1744	. .	35,761
1768	. .	55,000
1774	. .	78,304
1790	. .	105,400
1802	. .	140,000

A new species of sugar-cane, far more valuable than that formerly in use, has lately been introduced into Jamaica. It was first imported into the French islands of Guadaloupe and Martinique, from the islands of Bourbon and Mauritius, and is called the Bourbon or Otaheite Cane. It is much higher, and four times as large as the cane formerly grown exclusively. It will grow on boggy land, and yields one-third more sugar than the old cane; but the sugar is not of such a compact grain. The average expence of the cultivation of sugar is 20s. 10d. per cwt. independent of the interest of capital and the produce of rum. The works necessary for making 200 hogsheads of sugar annually cost £10,000 Jamaica currency; and an estate producing such a quantity, requires £40,000 to establish it, viz. 250 negroes at £70 sterling each, amounting to £17,500; 180 cattle and mules at £30 each, amounting to £5400; buildings for the manufacture, and houses for negroes and owners, £7000; and land, £10,100. The value of the buildings and machinery on the sugar plantations varies from £4000 to £25,000 sterling. The greatest crop of sugar on an estate with one set of works ever grown, was 1030 hogsheads, of 18 cwt. each; but estates in general, with one set of works, make from 100 to 300 hogsheads. Estates containing 1500 negroes and a due proportion of whites, require about £10,000 sterling of supplies annually of British manufactures and provisions. One hundred barrels of herrings are required for 250 negroes in the course of the year.

Produce, expence of cultivation, &c.

Produce, expence of cultivation, &c.

The following table, extracted from the Report of the Committee of the House of Commons in the year 1807, on the commercial state of the West Indies, exhibits the outgoings, and the produce of a sugar estate in 1806, which was cultivated by 519 negroes, and 434 head of stock.

OUTGOINGS.

British and Irish Supplies.

Lead, mill-work, and ironmongery utensils .	£671
Medicines, oil, tallow, grain, wine, &c. .	306
Osnaburghs, negro clothing, hats . .	516

PRODUCE.

	Hhds.	Tierces.
Sugar . . .	472 . . .	81
	Puncheons.	
Rum . . .	164	

Formerly it was calculated, that where two hogsheads of sugar were made, there was at least one puncheon of rum; but latterly the proportion has been greater; the average annual quantity of rum being nearly 54,000 puncheons.

Coffee.

Coffee was little cultivated in Jamaica till the year 1788. The coffee plantations are generally situated in the hilly regions, of which nearly two-thirds of the island consist, and which are, from their soil, climate, and situation, unfit for sugar plantations. The increase of coffee plantations may be seen from the following facts, taken from the report already referred to.

Cotton.

Indigo.

Ginger.

Pimento.

In the four years ending the 30th September 1791, the average exportation of coffee was 1,603,066 lbs.: in 1804, it amounted to 22 million pounds; and during three years ending 30th September 1807, the average exportation was more than 28½ millions, which, at £6 per cwt. its cost in Jamaica, produced more than £1,700,000. It is calculated that £20,000,000 is invested in coffee estates. Cotton is not cultivated to any very great extent: it was attempted to cultivate it on ground worn out by sugar; but it was found that such soil would not grow either cotton or coffee, and would produce only very inferior grass. Indigo is now very little cultivated, and, in all probability, will never again become a staple commodity. Blome, who published a short account of Jamaica, in the year 1672, mentions that there existed at that time, about 60 cocoa walks: at present, there is scarcely a single plantation in the whole island. Ginger is little cultivated. All the produce of the arnotto plant, which is at present exported from Jamaica, is gathered from the trees that grow spontaneously. The pimento trees also grow spontaneously, and in great abundance, especially in the hilly regions of the North. The returns from a pimento walk, in a favourable season, are very great: a single tree has been known to yield 150 lbs. of the raw fruit, or 100 lbs. of the dried spice.

The following Tables will further illustrate the value, and produce, and expence, of cultivating Jamaica estates at different periods.

Value of estates.

Common Valuation of an Estate.

	Sterling.
Cane land, the canes upon it valued separately	£22 per acre
Plants	22 do.
Cane land in ratoons and young plants	15 do.
Pasture land	8 do.

The annual value of the lumber and provisions formerly imported into Jamaica from the United States, amounted to above £ 1,000,000, in return for which, the Americans were allowed to take only rum and molasses. Of the former, they used to take annually 30,000 puncheons; but since they began to distil spirituous liquors themselves, they seldom take more than 5000 puncheons.

Importation and exportation of slaves.

The following Table exhibits the importation and exportation of slaves for four years, previous to the abolition of the slave trade.

Years.	Vessels from Africa.	Tonnage.	Crew.	Slaves imported.	Slaves exported again.

Official returns for 1812.

In the papers relative to the West Indies, ordered by the House of Commons to be printed, 12th July 1815, there is much important information respecting the statistics of several of the parishes of Jamaica, in the year 1812, the substance of which we shall give, as we shall thus exhibit the latest official statement on this subject.

In Kingston parish, the number of slaves assessed was 6840; but it was supposed there were considerably more: the free blacks of colour amounted to 8000: the extent of the city and parish from east to west is six miles; from north to south one and a half.

In Vere parish, the number of whites was 359; of free people of colour 260; of slaves 14,359; and the number of acres 128,597.

In Westmoreland parish, the number of white men was 432, women 129, boys 70, girls 57—in all 688: persons of colour, men 158, women 266, boys 175, girls 191—in all 790: free blacks, men 47, women 65, boys 1, girls 6—in all 119. The number of slaves was 21,019; of stock 20,575; and of acres 185,116½. In this parish, the increase of slaves in 1809 was, males 181, females 174—total 355; and the decrease, males 226, females 195—total 421; making the actual diminution of males 45, and of females 21—total 66. In the year 1810, the actual diminution was, males 28, females 16—total 44.

In the parish of St Thomas, the number of white males was 369, females 49, children 16; of slaves 26,341. The births of slaves in the December quarter of 1807 was 176, the deaths 543. The number of free persons in 1812 was, males 207, females 142, children 114; the number of acres 143,475.

In the parish of St George, the number of slaves was 13,233; their increase by births above deaths from 1800 to 1807, both years inclusive, was 196. Of free persons of colour, there were, in 1812, adult males 63, female 97; male children 103, female 80; in all 343. Free blacks, males 4, females 28. The number of acres in this parish is 92,927¾. The number of negroes returned in the parish of St Anne, was 23,261. In Portland parish there were 7651, of which 3949 were males, and 3702 females. The white population amounted to 415, of which there were males 217, females 96; boys 53, and girls 49. The free persons of colour amount to 180, of which there were, males 73, females 58; boys 23, and girls 26. The extent of this parish is nearly 20 miles. In 1810, the births of slaves were 94, the deaths 89; increase 5.

In the parish of St David's, the white population amounted to 131, of which there were, males 116, females 10, and children 5. The free persons amounted to 29, of which there were, males 5, females 11, and children 13. The number of slaves was 7203. The births of slaves in the December quarter of 1806 were 58, the deaths 56; increase 2. The number of acres in this parish is 46,619.

Slaves, stock, and cultivated acres in 1812.

The following Table exhibits the number of slaves, stock, and cultivated acres in all the parishes of Jamaica, in the year 1812, according to the return laid before parliament. The reader will observe that there is some difference, with respect to acres, between this Table and the previous statements, though both are taken from the same parliamentary papers.

Parishes.	Slaves.	Stock.	Acres.
St Andrew's	16,570	5,181	83,427
St Anne	23,702	24,537	230,224
St Catherine	8,479	6,868	68,281
Clarendon	20,228	9,564	221,847
St David	7,203	2,208	50,831
St Dorothy	5,130	2,958	36,743
St Elizabeth	22,280	23,237	276,838
St George	13,400	3,710	93,100
Hanover	23,167	7,201	105,198
St James	24,970	6,628	127,743

Kingston	5,370	604	1,786
St Mary	25,781	16,010	122,557
Portland	7,440	1,640	50,263
Port Royal	7,980	223	29,126
St Thomas in the East	26,291	5,374	143,475
Ditto in the Vale . . .	11,973	2,503	78,029
Trelawney	27,950	6,380	173,768
Vere	14,359	4,691	109,946
Westmoreland	21,109	12,769	85,413
	319,912	143,419	2;254,387

As the whole island is calculated to contain upwards of 4,000,000 acres, it appears from this Table that there is little more than half of it cultivated. Of the acres in cultivation, about 700,000 are under sugar lands, and nearly the same quantity in pasture.

Government.

The governor of Jamaica is appointed by the king, and can be recalled at pleasure; there is besides a council, and a house of assembly. The former is generally chosen by the crown from amongst the most respectable inhabitants; the members are twelve; they are *ex officio* justices of the peace, and form a privy council to the governor. The house of assembly consists of forty-three members, who are chosen by the freeholders; every parish sends two members, except Spanish Town, Kingston, and Port Royal, which send three each. The electors must be white, of age, and possess a freehold of ten pounds per annum in the parish. The representative must possess a freehold of £300 per annum in any part of the island, or a personal estate of £3000. The supreme court of judicature, called the grand court, and combining the jurisdiction of the courts of king's bench, common pleas, and exchequer in England, is held in Spanish Town on the last Tuesday of February, May, and November. Assize courts are held every three months in Kingston for the county of Surrey, and in Savannah la Mar for the county of Cornwall.

Revenues.

The revenues of the island are perpetual and annual. The former were imposed by the revenue law of 1782; they amount to about £12,000 per annum: the latter are occasional grants of the legislature. The principal taxes consist of a duty on negroes imported; an excise on rum, &c.; a poll tax on slaves and stock; and a rate on rents and wheel carriages. The revenue generally amounts to about £300,000 Jamaica currency.

Ecclesiastical establishment.

There are nineteen beneficed clergymen in the island, each of whom receives £420 per annum, subject to a deduction of 10 per cent. for a widows' fund. Besides this stipend, there are surplus fees, which in Kingston, Spanish Town, and St Andrews, are very great; the last has also considerable glebe lands annexed to the living.

Militia.

All white males, from the age of fifteen to sixty, are obliged by law to provide themselves with their own accoutrements, and to enlist either in the cavalry or infantry of the militia.

Coins.

Besides the Spanish and Portuguese coins, which are current in the island, there is a small silver coin called a *bit*, of the value of 7½d. currency. One hundred pounds sterling amounts to one hundred and forty pounds currency.

History.

Jamaica was discovered by Columbus in 1494; in 1509, it received a Spanish colony from Hispaniola; in 1655, all the establishments were abandoned except St Jago de la Vega. This year it was conquered by the English under Penn and Venables. The first British colonists were 3000 soldiers, disbanded from the parliamentary army. These were soon followed by 1500 royalists. Till the Restoration, the government was entirely military. On the surrender of the island to the English, the negro slaves of the Spaniards fled to the mountains; their descendants, called Maroons, committed great depredations till 1738, when a treaty was concluded with them, by which their freedom was secured, and 1500 acres of land granted to them. They remained peaceable till the year 1795, when a new Maroon war broke out; at first they were rather successful, but at last, by a more vigorous system of hostilities, and the introduction of bloodhounds from Cuba, with which they were threatened, though not actually attacked, they were driven to the mountains, and ultimately obliged to submit on condition that their lives were spared. Soon afterwards, 600 of them were conveyed to Nova Scotia, where lands were granted to them.

See Beckford's *Descriptive Account of Jamaica*; Edwards' *History of the West Indies*, 2d edit. vol. i.; Dallas' *History of the Maroon War*; Renny's *History of Jamaica*; Tuckey's *Maritime Geography*, vol. iv.; and *Parliamentary Reports and Papers on the West Indies*, 1807 and 1815. (J. S.)

IAMBIC VERSE. See PROSODY.

JAMES I. II. III. IV. V. VI. See the *History of* SCOTLAND.

JANIZARIES. See TURKEY.

JAN SEILAN, or JUNK CEYLON, is an island of Asia in the Bay of Bengal, situated on the west side of the Malay peninsula. It is separated from the continent by a narrow sandy isthmus, about a mile long and half a mile in breadth, which is covered at high water, and whereon spring tides rise 9 or 10 feet. This island is between 40 and 50 miles in length, about 15 in breadth, with good anchorage around its whole circuit, and it has an excellent harbour on the north called Popra, besides others. Its name, Jan Seilan, is of uncertain etymology, and it is frequently called Junk Ceylon by Europeans.

The climate here is particularly agreeable, for the heat is moderate. Rains begin to fall gently in July, and continue until November, with frequent intermissions of fine weather, attended with cool north-east winds at night. There is no considerable river in the island, both from its size, and the hills being low; but several streams run through flat marshes of mangroves into the sea.

A great quantity of tin is obtained in this island, of which about 500 tons are exported yearly. The produce was greater formerly; but it seems to have been reduced by restrictions on the miner, who was obliged to carry all his ore to a Chinese smelter farming this privilege from the government. Besides paying 12 per cent. for smelting, the miner could only obtain the metal on having delivered a certain quantity of ore, though the extract exceeded what he received, and after all a duty of 25 per cent. was payable previous to exportation.

The interior of the island contains large plains of rice well cultivated, and hither the inhabitants can come up the creeks in their small vessels; but the skirts are kept in a state of nature, for the purpose, it is supposed, of obstructing the access of an enemy. Rice is the staple product; and of other vegetables there are oranges, limes, and most of the tropical fruits and roots. The wild animals are deer and hogs: the domesticated ones are elephants, and a few goats; but the islanders have neither horses, sheep, dogs, nor cats, and their common poultry is not numerous.

The population of the whole island has been calculated at 12,000. This number, however, must be dependant on a state of peace or warfare, and during the latter it is probably lower. The features of the people resemble those of the Malays, intermixed with a good deal of the Chinese aspect. They are well made, but rather slender: they speak the Siamese language, and in general understand the Malay tongue: and, like Europeans, they write from left to right. Unrestrained polygamy is practised, as every man marries as many women as he can afford to maintain; but it is the privilege of the first wife to rule the household. No woman is permitted to leave the country.

The inhabitants are distributed in towns and villages, of which 16 are named, but all of them are inconsiderable. Terowa, the chief town, situated on a creek, where a strong current runs, consists only of about 80 houses. A wooden pagoda, covered with palm leaves, stands here, which is served by about 20 talapoins or monks, who live in a state of celibacy, and dwell in small apartments adjoining to it. Their heads are shaved and uncovered: they wear a yellow garment, and carry a white rod in their hands, but it appears that they can resign their monastic vocation at pleasure. The governor of Jan Seilan has also a dwelling at Terowa, and another eight miles inland.

Tin is the principal export of the island, which formerly carried on considerable commerce with several Asiatic ports; but this has greatly decreased since the establishment of a British colony on Penang. Its exports, besides that metal, are elephants teeth, biche demer, and sayhan. The imports are principally opium, a contraband article, for which there was a great demand about the middle of the preceding century; and after being carried in British vessels from Bengal, it was sold to the Malays and Buggess prows for the tin of the island. Hindostan piece goods, brass utensils of Java, European cloth and cutlery, were likewise among the imports. Commerce is injured, from a practice not unusual in the East, of the government or its officers being the principal dealers. Hence the king's merchant sometimes purchases a whole cargo on the arrival of a vessel, and immediately upon its being landed, retails it at a great profit. This impolitic interference restrains the competition and consequent advantages of unfettered commerce. The currency of the island consists of conic frustums of tin, of two or three pounds weight, with correspondent halves and quarters, which cannot be exported without payment of duty. Spanish dollars are the most acceptable money, but all kinds of Indian coinage pass current.

When the French had much interest at the court of Siam, one of the most powerful and brilliant of the East towards the latter part of the seventeenth century, they proposed to make a settlement in Jan Seilan. It is probable, that the benefit which would result from the presence of a commercial nation could be appreciated by a native of the Ionian islands, then prime minister of Siam, who was well acquainted with the trade and manufactures of Europe. But the history of this settlement, which we believe commenced in 1688, is not preserved; and it most probably terminated soon after the fall of that minister in 1689.

As this island is too small to maintain its independence, it must necessarily be controlled by the continental powers. It was long in the possession of the kingdom of Siam, and when visited by Captain Forrest in 1784, it was governed by a viceroy from that country, who had three associates or counsellors. Each of these officers had about sixty military retainers armed with a musquet and bayonet, sword and dagger, who, receiving little pay, lived in some respect on the community. The inhabitants being then dissatisfied with the imposts upon them, particularly with that which was laid upon their staple commodity, wished to shake off the yoke of Siam; but it is not known that they adopted any active proceedings. In the following year, 1785, the Birmans, who had for some time been extending their dominions, had gained so much territory on the continent, that, with the possession of Jan Seilan, they could have prevented the Siamese from any other channel of communication with India than the gulf of Siam. In order, therefore, to effect its conquest, they fitted out eleven ships of war at Rangoon for the conveyance of troops and warlike stores, while an army of 8000 men marched to Mergui, a port on the peninsula, for the purpose of cooperation. Having made a movement against the island in March, they attacked and carried the fort, which is situated on the east side, and found in it much valuable booty. But the governor, who had retired to the interior, rallied his forces, and compelled the enemy to retreat, after sustaining great loss. The Birmans, nevertheless, did not abandon their object, and after a long interval returned in 1810, when they effected the total conquest of Jan Seilan, and consigned the whole inhabitants to slavery in Pegu: At a still later period it continued to be the subject of contest between them and the Siamese. East Long. 94° 18′. North. Lat. from 7° 46′ to 8° 9′. (*c*)

JAPAN.

Japan.

Japanese islands, situation of.

The Japanese islands lie near the coast of Corea on the eastern side of Asia, in the North Pacific Ocean, between 31° and 41° of N. Lat. and 129° and 142° E. Long.

Empire of Japan, extent of.

The Empire of Japan is composed of an extensive cluster of islands, by much the largest and most important of which is called Niphon or Jepuen. This island is of a triangular form, and is upwards of 700 miles long, but does not exceed 80 miles in breadth. Adjoining to the south-west point of Niphon are Kiusiu or Saikoff, 140 miles long by 90 broad, and Sikoff, 95 miles long by 45 in breadth. The island of Jesso or Matzumay, on the north of Niphon, from which it is separated by the straits of Sangar, about nine miles in breadth, was conquered from its original inhabitants the Ainos, and is now also included in the Japanese dominions; but though larger than the two last, its dimensions are not mentioned by geographers. These are environed by other islands of inconsiderable size and note.

Discovery of.

The discovery of this extensive insular power, abounding in natural and artificial resources, and of an overflowing population, does not reach farther back than the middle of the 16th century. It appears that we are indebted to the travellers Rubruquis and Marco Polo for the first mention of the existence of this country. Fernando Mendez Pinto, sailing in a Chinese junk from Macao to the Likeo islands, was wrecked on the Japanese coast in 1542, and he accordingly has the merit of being the first European discoverer of Japan. Three other Portuguese dispute with Pinto this honour, pretending that they touched on the coast of Satzuma the same year; but luckily neither the year of discovery, nor the nation of the discoverer, is affected by this dispute.

Visits of Europeans.

Japan was soon after visited by the Spaniards, and (what is a singular circumstance) their first visit, like the original discovery of the island, was owing to a shipwreck. The governor of Manilla, on his voyage from New Spain, being wrecked in 1609 on the Japanese coast, was sent with his attendants by the Emperor of Japan to Acapulco. An embassy, with rich presents from the Spaniards to the emperor, followed in 1611. But all Christians being extirpated from his dominions, both Spaniards and Portuguese were excluded; nor has an intercourse been again attempted, although, from the vicinity of the Philippine islands, a commerce mutually advantageous might be expected. The Dutch, from their enterprizing spirit of trade, could not fail to regard Japan with a longing eye; and as no Europeans had acquired a permanent footing there, they were eager to push their commercial interests in that quarter. An accident favoured their views. In 1600 a squadron of five ships, which sailed from the Texel for the East Indies, was lost in the straits of Magellan, with the exception of one Dutch ship, steered by an Englishman of the name of William Adams, which reached the harbour of Bungo in Lat. 35° 30′. Adams was fortunate enough to ingratiate himself with the Emperor of Japan, who loaded him with presents, but would not consent to his returning home.

Establishment of the Dutch.

The accounts he sent to Batavia, with the prospects he held out of a beneficial commerce between the two countries, induced the Dutch East India Company to dispatch a ship thither in 1609; and thus, through the intervention of an individual, are the Dutch indebted for their establishment at Japan. They are the only people that have contrived to retain the favour of the Japanese, who, under humiliating restrictions, permit them to carry on a trade, limited to the dispatch of two small ships annually from Batavia to Japan. Nearly about the same time, the English also, by means of their countryman Adams, had permission to build a factory on the island of Firando; but though they were well received, and allowed to traffic on advantageous terms, the trade was abandoned for reasons hitherto unexplained. The Dutch thus remained the only European merchants in Japan.

Dutch policy.

In conformity with their policy, they endeavour to throw a veil of secrecy over the scene of their commercial pursuits, being probably apprehensive lest their transactions should be viewed in too strong a light. Notwithstanding this prohibition of intelligence, we have been furnished with full and pretty accurate details concerning the state of the Japanese islands.

Accounts of Japan.

In addition to the corrected accounts transmitted us by Kæmpfer and Thunberg, Captain Krusenstern, who was selected by the present Emperor of Russia to carry the Russian flag for the first time round the world, and on board whose ship an embassy was conveyed to Japan, has given us valuable information about the Japanese coasts and harbours.

Harbour of Nangasaky.

Although it appears that Japan has been visited for upwards of two centuries by different European nations, and the harbour of Nangasaky, one of the best in the world, has been annually frequented, yet no plan of it has been taken, nor have even the latitude and longitude been correctly ascertained, until it was explored by Krusenstern in 1804.

Description of.

The entrance of the harbour of Nangasaky is in 32° 43′ 45″ N. Lat. and 230° 15′ W. Long. in the middle of the bay of Kiusiu, which is formed by Cape Nomo to the south, and Cape Seurote to the north. The entrance bears 51 miles E. by N. from Cape Gotto in 32° 34′ 50″. It is necessary to ascertain correctly the true entrance; for, by steering on Cape Nomo, there is danger of being becalmed, or driven by the tides on the rocks, and of mistaking another entrance in Lat. 32° 40′, which has not been explored. The safest course is to keep midway between the Gotto islands and Kiusiu, steering N. E. until the parallel of the entrance, and then, due east. The harbour contains three roads, all perfectly secure. The outermost is to the west of the island of Papenberg, the second in the middle to the eastward of the same, and the inner road at the bottom of the harbour in front of the city. The outer road is well defended from every wind but the N. W. and W. N. W. which, however, never blow very strong. The anchorage is excellent, over a bottom of fine grey sand, in depths varying from 33 to 18 fathoms. The middle road is surrounded on all sides by the land, and has better anchoring ground than the inner, but not so good as the outer road. From the middle to the inner road the course lies N. E. 40°, and the distance is about two miles and one-third, the depth of water decreasing gradually from 18 to 5 fathoms. About half way, where the channel narrows to 400 fathoms, are placed the imperial batteries or Emperor's guard, as they are styled, a number of buildings without a single cannon. From the narrowness of the approach, the city of Nangasaky, if well fortified, could defy any assault; in its present state it would fall before a single ship of force. The anchorage here is not equal to either of the other roads, the bottom being a thin clay, and the S. W. channel open to the sea. Krusenstern was the only person, except La Perouse, who navigated the western coast between Niphon and the Corea; and although the state of the weather was unfavourable to his making observations, yet he appears to have reached the northern point of Jesso, the extreme limit of the Japanese empire, without much difficulty.

Japanese coasts, general character of.

Of the Japanese coasts it may be observed generally, that they are in most places rocky and precipitous, presenting a chain of bold promontories, deep bays, and rugged peninsulas, abounding with shoals and islets, the whole invested with a turbulent sea; whence the navigation is intricate and dangerous.

Climate.

The climate of Japan is variable throughout the year. The heat of summer would be insupportable, were it not moderated by the sea breezes. The rainy months begin at midsummer, when abundance of rain falls, and to which is to be ascribed the fertility of the country. In winter, the wind blowing from the Arctic Ocean, makes the cold severe. Snow falls in quantities, and is followed by intense frost. Hurricanes and earthquakes are not uncommon, and thunder storms also frequently occur.

State of thermometer.

At Nangasaky, the thermometer was never in August higher than 98°, nor in January lower than 35°.

Rivers.

As the geography of Japan has not been fully illustrated, we can give but an imperfect account of the rivers, lakes, and mountains of this country. The largest river is said to be the Jodo or Yodo, which rises from the great central lake of Oitz, and pursues a south-west course. The Ujin, Aska, and Oomi, figure in Japanese history. This last is said to have burst from the ground in one night. Over the Nogofa and Jedogawa are projected cedar bridges from 300 to 360 feet long. There are various other rivers, of which we know little except the name. The above mentioned lake of

Mountains, volcanoes, &c.

Oitz sends forth two rivers, and is said to be 50 Japanese leagues in length, but of inconsiderable breadth. Among the mountains are volcanoes, and in the province of Figo one constantly emits flame. The principal mountain is Fusi, which is covered with snow the greatest part of the year. But the courses of the different ranges have not been traced. Near the lake of Oitz is the sacred mountain of Jesan, said to be decorated with 3000 temples!

Division into provinces, &c.

Aspect of the country.

Agriculture.

Crops.

The Japanese islands are divided into provinces and districts, like other civilized countries. The face of the country of Japan is agreeably diversified by mountains, hills, and vallies, and is well watered with rivers and lakes, the general aspect presenting a soil cultivated with industry and freedom. Even mountains and hills form no obstacle to cultivation. Agriculture being in high estimation in Japan, it meets with the greatest encouragement from the government.* The chief produce is rice, barley and wheat being little used. A kind of potatoe is common, and several sorts of beans and peas, turnips and cabbage, abound. The rice is sown in April, and gathered in November. The sides of the hills present a singular spectacle to the stranger, from the mode of cultivation which is adopted. Stone walls support level platforms sown with rice or roots; and thousands of these are scattered over the mountains, affording a favourable picture of the ingenuity and industry of the inhabitants. Though the space should not exceed two square feet, a stone wall is raised at the bottom, the inclosure filled with earth, and carefully sown with rice, or planted with esculent roots. As may be easily supposed from this state of general cultivation, few forests are suffered to grow: these are confined to the sides of such mountains, probably, as can be subdued by neither agricultural labour nor skill.

Mode of cultivating the hills.

There are no fences used in dividing the cultivated grounds in this country; and the fields often resemble kitchen gardens divided into narrow beds, which are separated from each other by a deep trench, nearly as broad as the divisions which are under crop. After a certain interval the trenches are filled up with earth, so as to be converted in their turn into beds, and give the soil a rest from constant bearing. In these beds the corn is sown sometimes lengthwise, but more commonly across; and after the crop is cut down, another kind of grain is sown in the same season, between the stubble of the old crop, so as to make the same field produce twice in one year. The greatest care is bestowed upon manuring and cleaning the ground. Every kind of substance which can be converted into manure is carefully collected; and, together with urine and foul water from the kitchen, is mixed up in a liquid state. It is then carried in large pails to the fields, and, by means of a ladle, it is poured upon the plant after it is about six inches in height. Irrigation also is much practised, wherever water can be procured in the vicinity of the fields. The weeds are so completely cleared away, that "the most quick-sighted botanist," says Thunberg, "would scarcely be able to discover a single plant of another species among the corn." The grain is frequently separated from the straw merely by beating the sheaves against a post or barrel; but is commonly threshed on straw mats in the open air by means of flails with three swingles. There are no pasture grounds among the cultivated tracts; and the few cattle used in the country are all fed in the farm-yards. Thunberg affirms, that the soil throughout Japan is naturally barren, and has been rendered so remarkably productive only by the labour and skill of the husbandman.

Vegetable productions.

Japan abounds in rare and beautiful plants; and as there is a great similarity in the vegetable productions of China and this kingdom, no doubt from the vicinity of the two countries, they are mutually indebted to each other for an interchange of useful vegetables. The ginger, soy bean, black pepper, sugar, the cotton and indigo plant, though not indigenous, are cultivated with success, and in abundance, in Japan. Two sorts of mulberry grow; one which feeds the silk worm, and the other is manufactured into paper. It is said that the beautiful black varnish is produced from a gum which exudes from the bark of the rhus vernix. The citrus japonica, a species of orange peculiar to this country, is found in a wild state. But as the botany of Japan has been treated at length by Kæmpfer and Thunberg, our botanical readers are referred to them for particulars on this subject.

Mines.

Gold, silver, and especially copper, are found in abundance in Japan, large quantities of which have been exported at various times by the Portuguese and Dutch. No mine can be opened without the permission of the emperor, who claims two thirds of the produce, leaving only one third to the proprietor for his expences. Iron is scarcer than other metals, and the Japanese will not allow it to be exported.

Sulphur is found in sufficient abundance, particularly in a certain island near Satsuma; and pit-coal is not uncommon in the northern provinces. Red agate, asbestos, porcelain clay, flesh-coloured steatite, pumice stone and white marble are also found in Japan; and there are several warm mineral waters, especially at Obamma and the mountain of Omfen, which are used by the natives in the cure of various diseases.

Animals.

It is singular that neither sheep nor goats are propagated in the Japanese dominions. The latter, and swine, are deemed destructive of cultivation. Horses are rare, and cattle still more so, these last being reserved solely for agricultural purposes. Buffaloes with a bunch on their backs are sometimes seen employed in drawing carts. The cows are very small in size, and are used rather for draught than for their milk or their flesh. Dogs are common in the domestic state, and are said to be kept from superstitious motives. Cats of various colours are to be seen in every house, and are said to be the general favourites of the ladies. The wolf is found in the northern parts, and foxes in different districts, but are regarded with peculiar detestation, as demons incarnate. Hares of a grey colour, and rats as in other countries, have been seen by travellers in Japan; and, in the least inhabited tracts, bears, monkeys, deer, &c. are reported to be found. The common kinds of poultry are reared in considerable abundance; and great numbers of wild geese frequent the waters between the islands, and other places at a distance from the towns or villages. Herons are seen following the ploughman in the fields; and the Chinese teal, the quail, the crow, pigeon, and bulfinch, were all observed by Thunberg. Serpents are said by the natives to be occasionally seen; but few of the amphibia are met with in the country. Fish, which are an

---

* The farmer pays a considerable part of the produce as rent to his feudal chief, and is restricted only to one condition, viz. to have all his land in cultivation. Should he leave any part of his fields untilled, he forfeits the possession of that portion, which is occupied by another husbandman.

important object to the Japanese, and a principal part of their subsistence, are very numerous around the coasts, especially salmon, perch, eels, shrimps, oysters, crabs; and the flesh of the whales, which are killed by harpoons, is sold in the markets as an ordinary article of food among the poorer people. Many curious shells, especially those that were of a small size and elegant shape, are collected by the Japanese, fixed with rice-glue upon carded cotton, and sold to the Dutch traders.

Natives. The original population of Japan has been little illustrated. The present Japanese seem to be a kindred race with the Chinese, having at the same time, according to Kæmpfer, a language radically distinct. Perhaps, in the earlier stages of society, as is observed by Pinkerton, the Japanese may have emigrated from China, and their complete insular separation may have given birth to a language rendered peculiar by the progress of a distinct civilization. **Described by Thunberg.** The people of this nation are described by Thunberg to be well made, active, free and easy in their motions, and stout limbed, though yielding in strength to the northern inhabitants of Europe. The men are middle sized, and in general not corpulent, all over of a yellowish colour; in some brown, in others white predominates. The lower classes, from exposure to the sun, are brown, but ladies of distinction, who seldom go abroad uncovered, are perfectly white. **Discriminating mark, the eye.** The discriminating mark of the Japanese, as of the Chinese, is the eye. This organ wants its characteristic rotundity, being oblong, small, and sunk deep in the head, whence these people have the appearance of being pink-eyed. The colour of their eyes, however, is dark brown, or rather black; and the eyelid forming a deep furrow, makes the Japanese look sharpsighted. Their head is in general large, their neck short, and their hair black, thick, and shining from the use of oils.

They are said to be an intelligent and provident people, inquisitive and ingenious, frugal and sober, friendly and courteous, frank and good humoured, upright and honest, brave and unyielding, capable of concealing and controuling their feelings in an extraordinary degree; but distrustful, proud, unforgiving, and revengeful.

Dress. The usual dress of the Japanese is a short upper garment with wide sleeves, and a complete gown underneath, fastened round the neck, and reaching quite down to the feet; the dress much resembling that of European females, except in being more confined from the hips downwards, which produces great embarrassment in walking. But this exercise is seldom resorted to by a Japanese, except from compulsion. The rich are clothed in silks, the poor in coarse woollen stuffs. The upper garment is generally black, the under dress is of mixed colours. **Family arms, how worn.** Every one has his family arms, about the size of a half dollar, wrought into his clothes in different places, a practice common to both sexes. Thus persons of a particular family may be easily recognized. A young lady wears her father's arms till after marriage, when she assumes those of her husband. The greatest honour a prince or governor can confer, is to present a cloak with his arms upon it; and the person who is thus honoured puts his own arms upon some under part of his dress. In winter they wear five or six dresses over each other; but though the weather is bad in January and February, they use neither cloth nor furs in their apparel. Instead of shoes they have soles merely of straw, fastened to the great toe by a loop, and these are taken off when they enter a room. Although they have their heads half shorn, they are regardless of a burning sun, or piercing cold. They do not use parasols in sunshine, nor umbrellas in rainy weather; but in travelling, conical caps, fans, umbrellas, and cloaks of oiled paper, are very commonly used. **Toilet.** The toilets of the Japanese must occupy a considerable share of attention, as they are very particular in anointing and dressing their hair, which is collected in a tuft on the crown of the head. Small pincers are employed to pluck out the hairs on their chin, and these, with a small metal looking mirror, are found in the possession of every Japanese. **Remarkable cleanliness of person.** They cannot be denied, Krusenstern observes, to study great cleanliness of person, although they make no use of linen; and this appears a governing propensity of the Japanese of every rank. Hence, in almost every house, a bath forms an essential part of domestic arrangement and comfort. But in one respect their customs are extremely offensive. The privies, which are also indispensible in every house, are all built towards the street or road, and open outwards, exhibiting large jars sunk in the earth, to receive every kind of ordure and refuse. Hence the stench is insupportable, and the putrid exhalations, as Thunberg affirms, injurious to the eyes of the natives.

Houses, construction of. In Japan the houses are of wood, never exceeding two stories, the upper one consisting chiefly of garrets and lumber rooms. Though the house is commodious, it consists in general of one room, capable, by moveable partitions, and screens, of being divided into apartments. Neither tables nor chairs are used, the people sitting squat on straw mats, in which position they eat their food.

Diet. The diet of the Japanese is composed of a greater variety of articles than that of any other people in the world. Not contented with the numerous kinds of wholesome and nutritive food supplied by the produce of their lands and waters, they contrive, by their modes of preparing their victuals, to render the less valuable and even the poisonous parts of animal and vegetable substances useful, or at least harmless articles of subsistence. Their meats are cut into small pieces, thoroughly stewed or boiled, and always highly seasoned with strong spices and sauces. At their meals, the company are seated on the floor-mats, with a small square table before each person, whose portion is served up in neat vessels of porcelain, or of japanned wood, which are tolerably large basons, always furnished with lids. The guests salute each other with a low bow before they begin to eat; and, like the Chinese, take up the food by means of two small pieces of wood, held between the fingers of the right hand, and used with great dexterity, so as to pick up the smallest grain of rice. Between each dish they drink warm sacki, or rice beer, out of shallow saucers, and at the same time occasionally take a bit of a hard boiled egg. Some of the most common dishes are fish boiled with onions and a kind of small beans, or dressed with oil; fowls, stewed and prepared in numerous modes; and boiled rice, which supplies the place of bread for all their provisions. Oils, mushrooms, carrots, and various bulbous roots are used in making up their dishes. Tea and rice beer are the only liquors used by the Japanese; and it is with difficulty that they can be persuaded to taste wines or spirits. The sacki, or rice beer, heats and inebriates when taken to any extent, but the intoxication which it produces passes off speedily. Tea, which is always ready, is the usual beverage for quenching thirst. It is customary to eat three times a day; at eight o'clock in the morning, two in the afternoon, and eight in the evening. The women eat by themselves, apart from the men. The practice of smoking tobacco, which is supposed to have been introduced into Japan by the Portuguese, is very common with both sexes. Their pipes are very short, seldom more than six inches in length, and scarcely contain half a thimble full of tobacco. The stem is made of lackered bamboo, and the mouth-piece and bowl of copper. They are smoked out by a very few whiffs, and require to be repeatedly filled. The apparatus used by persons of distinction consists of an oblong box, about eighteen inches in length and a foot in breadth, of a brown or black colour, which contains, besides pipes and tobacco, three cups; one, which is lined with brass, for holding a live coal to light the pipe, another to receive the ashes of the tobacco, and a third to serve as a spit-box. At visits, this apparatus is the first thing that is placed before the guests, and is sometimes carried by a servant to places where tobacco is not expected to be presented. The poorer classes have their tobacco pouch and pipe slung to their girdle by a silken cord.

Polygamy permitted.

Polygamy is allowed in Japan, as in other Asiatic countries; though, in general, all but one female, who is acknowledged a wife, are merely regarded as concubines. This, of course, applies to the higher classes; the poor can only maintain one woman. The husband here, as in all eastern countries, exerts a complete despotism, but the wives are not so closely shut up as in China. Married women distinguish themselves in some places by painting their teeth black, and in others by pulling out the hair of their eye-brows. They are known also by wearing the knot of their girdle before, while others have it behind. Marriages are solemnized in the open air, in the presence of the priests and relations of the parties, without much pomp or solemnity. The bridegroom and bride advance together to an altar, erected for the purpose, with a torch in their hands, and, while the priest reads a form of prayer, the latter, having lighted her torch at a burning lamp, holds it out to the bridegroom, who lights his torch from hers. The guests then congratulate the new married couple, and the ceremony is concluded. The suitor makes a present to the father-in-law before obtaining his daughter; so that the more daughters a man has, and the handsomer their persons, so much the richer is he esteemed. The women often paint their lips with a violet colour; and are described by Thunberg as not remarkable for modesty. Nor are they the less esteemed for having served in the public brothels, establishments which are found in every town and village.

Funeral obsequies.

The bodies of persons of distinction are burned, while others are interred. The funeral pile is erected in a small house of stone fitted for the purpose, and provided with a chimney. The body is brought thither accompanied by men and women, and attended by a numerous train of priests, who are continually occupied in singing. Upon reaching the place for burning, one of the priests sings the eulogy of the deceased, and having thrice waved a lighted torch over the body, throws it away. It is then picked up by one of the children, or other relatives of the deceased, and applied to the funeral pile. The ashes are carried away in a costly vessel, and preserved for some time in the house, but afterwards are buried in the earth. Those who are not burned, are inclosed in a wooden chest, and let down into a grave in the customary manner. Fragrant spices are cast into the grave, and flowers planted on the earth which covers it. The surviving relatives visit the tombs of their friends for many years after their death, and sometimes during the whole of their lives, besides observing, as in China, the feast of lanthorns in honour of the dead.

Festivals.

In every superstitious country, we find the celebration of festivals attended by a relaxation of public morals, but in Japan a salutary check is imposed upon an abandonment to licentiousness by a wise regulation, prohibiting the celebration of national feasts for days successively. In conformity with this law, the feast called Kermes is held on the 11th, 13th, and 15th days of October. Krusenstern mentions a feast celebrated on the 1st of April called Mussume Matzury, on which occasion parents present dolls to their children. Trifling as the object of this festival appears, the Japanese seem to regard it otherwise, as they gravely requested the suspension of the work of the ship carpenters ashore during its celebration, which consists in dances, dramatic representations, and magnificent processions. The usual holidays in Japan are the first day of every month, when they rise early, dress in their best clothes, and visit their superiors or friends to wish them joy of the new moon; the fifteenth day, when the moon is at the full; and the twenty-eighth day, or the day before the new month. Besides these monthly festivals, they celebrate five others which happen only once in the year, namely, the first day of the new year; the third day of the third month; the fifth day of the fifth month; the seventh day of the seventh month; and the ninth day of the ninth month. These, which are all uneven numbers, are regarded by the Japanese as unlucky days; and, therefore, laying aside all business, they are dedicated to mirth and mutual congratulations. On some of these days, in preference to ordinary days, they choose to celebrate their nuptials, and to give their entertainments. Their amusements on these occasions consist chiefly in dramatic representations and dances. In their theatres, the spectators sit on benches fronting the stage, which is a little elevated, but so small and narrow as seldom to allow room for more than one or two actors at a time. They generally represent some great exploit or love story of their divinities and heroes, which are frequently composed in verse, and sometimes accompanied with music. No machinery or decorations are brought forward; but the chief part of the amusement seems to consist in the frightful dresses and uncouth contortions of the actors. The dances at private entertainments are performed by young women and boys hired for the purpose, who exhibit a variety of pantomimical gestures and evolutions, expressive of some heroic action or love intrigue, regulating their steps at the same time by the music.

Religion, and modes of worship.

The most prevalent religious sects in Japan, are those of Sinto and Budsdo. That of Sinto, which is the most ancient, though its adherents are now least numerous, is conceived to have originated from Babylonian emigrants, and to have been originally very simple and pure in its tenets. Its followers acknowledge a Supreme Being, who inhabits the highest heavens, and who is far too great to require their worship; but they admit a multitude of inferior divinities, who exercise dominion over the earth, water, air, &c. and have great power in promoting the happiness or misery of the human race. They have some conception of the soul's immortality, and believe, that a happy abode immediately under heaven is assigned to the spirits of the virtuous, while those of the wicked shall be doomed to wander to and fro under the firmament. Their practical precepts are directed to inculcate a virtuous life, and

Religion, and modes of worship.

obedience to the laws of the sovereign. They abstain from animal food, and are reluctant to shed blood, or even to touch a dead body. Their churches contain no visible idols, nor any representation of the Supreme Being, but sometimes a small image is kept in a box, to represent some inferior divinity to whom the temple is consecrated. In the centre of the temple is frequently placed a large mirror, made of well polished cast metal, which is designed to remind the worshippers, that in like manner as their personal blemishes are therein displayed, so are their secret evil thoughts exposed to the all-searching eyes of the immortal gods. The worshippers approach these temples with great devotion of manner, and with the most scrupulous attention to cleanliness of person and apparel. Advancing reverently to the mirror, they bow themselves to the ground, prefer their prayers, present their offerings, and then repair to their amusements. The Kubo professes himself to belong to this sect, and is bound to make a visit annually in person, or by an ambassador, to one of their temples, to perform his devotion, and present gifts.

Budsdo's doctrine was brought originally from the coast of Malabar, and is considered the same with that of Budha in Hindostan. Passing from China into Japan, it became blended with that of Sinto, and gave birth to a monstrous mixture of superstitions. Its peculiar tenets are, that the souls of men and of beasts are equally immortal, and that the souls of the wicked are condemned to undergo punishment and purification, by passing after death into the bodies of the lower animals. There are many other sects, very opposite in their tenets and observances; but they are said to live together in great harmony, or rather to share in all their mutual superstitions. The Dairi, or ecclesiastical sovereign, seems to be the general head of all those different sects, and appoints the principal priests throughout the country. Every sect has its respective church, and peculiar idols, which are commonly remarkable for their uncouth and hideous form. Thunberg mentions one colossal wooden image, which measures ten yards across the shoulders, and affords room for six men to sit upon its wrist. The inferior divinities are innumerable, as almost every trade has its tutelar god; and in one temple not less than 33,333 are said to be ranged around the supreme deity. The temples are commonly built in the suburbs of the town, on the most elevated and suitable spots, to which are frequently attached beautiful avenues of cypress trees, with handsome gates. The idols are usually exhibited upon an altar surrounded with flowers, incense, and other decorations. They are filled with the lower or secular priests, who attend to keep them clean, to light the lamps and fires, to present the flowers and incense, and to admit worshippers at all times of the day. Even strangers are allowed to enter, and sometimes to lodge in the temples. To some of the more noted churches it is common to perform pilgrimages, especially to the temple of Tsie, the most ancient in the empire, and almost completely decayed with age, notwithstanding the utmost care to preserve its ruins. Its sole ornaments are a mirror, denoting that nothing can be hid from the supreme being, and slips of white paper hung round the walls, to signify that nothing but what is pure should approach his presence. To this place the emperor must send an ambassador on the first day of every month, and every individual must make a visit, at least once in the course of his life. Such a pilgrimage, besides its general merit, is rewarded with an indulgence, or remission of sins for a whole year. There are also in Japan orders of monks or nuns; one of which consists of blind persons, a kind of beggars dispersed over the empire, and another called monks of the mountain, are a species of fortune tellers and quack-doctors, who are bound to live on roots and herbs, to practise constant ablutions, and to traverse deserts and mountains once in the year. There are likewise several philosophical sects in the country who disclaim all external worship; one of the most celebrated of which adopts the tenets of the Chinese Confucius, and resembles in its general principles the ancient school of Epicurus. Its followers acknowledge a kind of *anima mundi*, but limit the existence of man to the present life; and inculcate the general practice of virtue, but allow and even applaud the commission of suicide. Almost immediately after the discovery of Japan by the Portuguese, the Christian religion was introduced into the country by the Jesuit missionaries in the year 1549; and made such rapid progress that several princes of the empire were soon ranked among its converts, and about the year 1582, a public embassy was sent from the Japanese court with letters and valuable presents to the Roman pontiff. But the Portuguese who had settled in great numbers in Japan, intoxicated by the extent of their commerce, and the success of their religion, became so obnoxious to the natives by their avaricious and domineering conduct, that the representations of the heathen priests became at length sufficiently powerful to procure a prohibition from the emperor against the new religion, which threatened to overturn all the ancient institutions of the country. A violent persecution was commenced against the Christians, of whom 20,000 are said to have been put to death in the year 1590. Still did the number of proselytes continue to increase, and in 1591 and 1592, twelve thousand were converted and baptized. One of the emperors, named Kubo Fide Jori, with his whole court and army, embraced the Christian name; and had the Portuguese settlers in the country acted with ordinary prudence and gentleness, their cause must have triumphed; but the insolence of some of their prelates to some prince of the blood, became so insupportable, that a new persecution arose in the year 1596, which was carried on without intermission for the space of 40 years, and ended in the year 1638 with the total extermination of the Christians, and the banishment of the Portuguese from the country. The Japanese government, considering the unwarrantable conduct of these settlers to be inseparable from their principles as Christians, have persevered in the enforcement of the most efficacious measures to prevent their re-introduction into the country; and in order to detect any concealed adherent of these proscribed sentiments, all persons are required to prove their freedom from such heresy, by publicly trampling, at the festival of the new year, upon the images of the Catholic saints.

Form of government.

The form of government at present in Japan is pure despotism, to the exclusion of pontifical interference in the executive part. But as the Dairis, or spiritual monarchs, reigned through a long period of hereditary succession, we can only account for the ascendancy of the secular princes, by supposing that the former, resigning themselves to the more congenial and pleasing cares of religion, held the reins of government with a feeble hand. This change was effected not without bloodshed and commotion. The veneration with which the Dairi are still regarded resembles the

Form of government.

honours paid to the gods themselves. His person is considered as too sacred to be exposed to the air and sun, and still less to the view of any human creature. He never passes beyond the precincts of his court; and if he is at any time under an absolute necessity of going out of his palace, he is generally borne on men's shoulders that he may not touch the earth. His hair, nails, and beard are never suffered to be cut or cleaned, unless by stealth, and while he is asleep. He never eats twice from the same plate, and all the vessels once used in his meals, which are purposely of an inferior kind of porcelain, are usually broken to pieces, that they may not be profaned by unhallowed hands. His attendants are with few exceptions selected from his own kindred; and beyond the precincts of his court few persons know even his name till long after his death. Since the retrenchment of his power he derives his revenues from the town and district of Miaco, from an allowance out of the Kubo's treasury, and from the large sums which he acquires by conferring titles of honour. This ecclesiastical court is likewise the principal seat of literature, and may be considered as the only university in the empire. The students are maintained and instructed at his expence in the history of the country, mathematics, poetry, music, &c. The Kubos, or secular emperors, now reign in hereditary succession. Each province of the empire is governed by a prince, who is responsible to the emperor for his administration. He enjoys the revenues of his government, keeps his court, and defrays all the civil expences. Such an order of things appears to us only safe against turbulence and faction by powerful checks. Perhaps it is secured in Japan, by mutual jealousy, and the impressions of unlimited submission to the emperor, a feature of character peculiarly Asiatic.

Laws.

Thunberg informs us, that the laws of Japan are few, but rigidly enforced, without regard to persons. We have little acquaintance, however, with the Japanese code. We are told that most crimes are punished with death, and that none may incur this from ignorance, a brief code in large characters is posted up in every town and village, and regularly read in the temples. This, however, respects rather the crimes prohibited than the penalties annexed, which are said to be in some cases purposely kept unknown, and this uncertainty they affirm to have a salutary effect in deterring offenders.

Arts and sciences.

The Japanese have been celebrated for their proficiency in the arts and sciences. Perhaps the safest standard of comparison, in this respect, will be their neighbours the Chinese. They excel in manufactures of silk and cotton. Their swords are of curious workmanship. Their varnish is well known as inimitable, but for this they are chiefly indebted to the vegetable, from which it is made. The Japanese cultivate music, painting, drawing, geography, astronomy, and history. They are totally unacquainted with anatomy; and have no farther knowledge of natural philosophy and chemistry than a few notions gathered from European physicians. Their surgery consists almost entirely in burning pellets of moxa (or the leaves of mugwort rubbed soft like cotton) upon the place which is supposed to be the seat of disease; and thus forming an issue, which is kept open for some time. They also puncture with a silver needle where pains are felt. Krusenstern mentions that one of the talks, (or interpreters of the Dutch language) knew that Teneriffe belonged to the Canary Islands, and St Catherines to Brazil; from which we may conclude that they are no despicable geographers for Asiatics. Their drawings, we suspect, may challenge competition with those of China, like them, bidding defiance to perspective; and so scrupulous are they in copying from originals, that ugliness meets with no flattery from their portrait painters. Though we are not acquainted with the exact extent of their astronomical knowledge, we know that there is a set of people, called Issis, inhabiting temples near Jeddo, who foretel eclipses of the sun and moon. Their predictions are inserted in calendars, of which two sorts are published annually at Jeddo, one complete for the rich, and another abbreviated for the poor. Their art of printing is confined to the use of blocks, with which they impress only one side of the paper.

Schools.

Schools generally abound, and corporal punishment, it is said, is not introduced into their system of education. Their children are stimulated to emulation, and worthy achievements, by the recital of songs in praise of their deceased heroes. A few of the more studious acquire the Chinese language, and some of the physicians are able to understand the Dutch, and even the Latin. They have some knowledge of engraving; and are tolerably versed in the practical part of surveying, so as to possess pretty accurate maps of their own country and its towns.

Manufactures.

Their artificers work very skilfully in iron and copper, and in a mixture of gold and copper, called sowas, which they have the art of staining black or blue by means of their ink. They excel in the fabrication of steel instruments, and their swords are of incomparable proof. They are acquainted with the art of making glass, and grinding it for telescopes; with the construction of watches which they learned from their European visitors; and with the manufacture of paper from the bark of the mulberry tree. Their silk and cotton stuffs are equal, and often superior to similar productions of other eastern countries; and their laquering or varnishing in wood surpasses all the attempts which have ever been made in that department by any other people in the world.

Varnish.

This varnish is made from the juice of the rhus vernix, which upon its first exuding from the tree, is of a lightish colour, and of the consistence of cream; but the surface exposed to the air immediately becomes black. It is of so transparent a nature, that when it is laid unmixed upon boxes, and other articles of furniture, every vein of the wood may be clearly seen. But they make it of various colours, especially black or red, by mixing it with powdered substances of these colours. They apply it with a brush, and with as smooth a surface as possible; and when well dried in the sun it becomes harder than the board on which it is laid. It is then rubbed with a smooth stone and water, till completely polished, when it is covered with a mixture of turpentine oil. This varnish flies and cracks like glass when struck with a hard substance; but is capable of being exposed to boiling water without receiving any damage.

Chief cities.

Jeddo, the capital city, is situated in a bay on the south-east side of the island of Niphon. As Europeans have little freedom here, no accurate idea can be formed of its extent. A large river runs through it. The emperor's palace and its appendages compose of themselves a town. It may be included among metropolitan cities of the first class, in point of size. Miaco, the second city of the empire, stands inland about 160 miles south-west of Jeddo. It is the first commercial and manufacturing city in these dominions. Here is fixed the Dairi's palace and court, whence

Miaco may be considered the seat of the arts and sciences. Its population has been rated at about 400,000 souls, and that of the capital at half a million. We do not vouch for the accuracy of this computation. There are from 30 to 40 other cities, of which the greatest part are flourishing, and of considerable extent.

Edifices.

The imperial palace, and edifices of the nobility, seem almost to rival in splendour those of China. The saloon of the hundred mats is 600 feet long by 300 broad. Cedar, camphor, and other precious woods, are employed in the pillars and ceilings.

Public roads and travelling.

The public roads are constructed and kept with great care. They are made very broad, with a ditch on each side to carry off the water; and are frequently bordered with hedges, which sometimes are formed of the tea-shrub. Posts are regularly erected to indicate the miles, which are all measured from the capital, and also to direct the traveller at every cross road. At the time when the princes of the country make their annual journey to the court, the roads are freed from every kind of dirt, sprinkled with water in hot weather, and sometimes even swept with brooms. In travelling on these roads, it is the rule for all who are going towards the capital to keep to the left, and for those who move in an opposite direction to take the right; or rather for each passenger to keep always to the side on his left hand. The roads are more easily preserved in so good a state, as no wheel-carriages are used in the country for travelling, except a few carts near the capital, which are confined to one side of the highway; and the horses are commonly provided with straw covers to their feet, instead of iron shoes. The poorer classes travel on foot, and others either on horseback or in palankeens. Several persons, and sometimes a whole family, are mounted on one horse. In such cases, the man sits on the saddle with his legs extended forwards on each side of the horse's neck, and the rest of the party are carried in baskets on each side, while a person walks before to lead the animal. The palankeens, or Kangoes and Norimons as they are called in Japan, are of various sizes; but the better kind are so large, that the traveller may lie down, or sit at his ease, on stuffed mattrasses and cushions. There are windows in the sides, and various conveniences within these vehicles. The pole by which they are carried passes along the roof, and is borne on the shoulders of the bearers, who generally keep time by a song, and travel at the rate of a league in the hour, or ten leagues in the day. When any of the grandees is going to court through the streets of the capital, it is the fashion for his bearers to carry the pole aloft on their hands, and to move at the utmost speed in their power.

Population.

As we have no certain data on which to estimate the population of the Japanese empire, we feel more at a loss on this branch of our subject than any other. Some hold China to be a fair standard of reference for Japan, and accordingly assign 30,000,000 as the proportionate amount. Others are content to rate the population at little more than half of this estimate; yet, as all travellers agree in stating that an overflowing population is seen moving about the streets and highways, we must reckon Japan one of the most populous countries, in proportion to the extent of surface, in the world.

Military force.

The same difficulty occurs in stating the military force of the kingdom. Some compute the army at 400,000 men, we know not how correctly. According to our ideas of a navy, the Japanese may be said to have none! The arms of the military consist of bows and arrows, scymitars and halberts. Their bows are large, and the arrows of great length; and the soldier, in discharging them, places himself with one knee upon the ground. The scymitar is their chief weapon, and is worn by all except the peasantry. The blade is about a yard in length, and slightly curved; so excellently tempered, that they are said to cut a large iron nail asunder, without their edge being turned, and are considered by the Japanese as the most valuable part of their property. They make little use of fire-arms, and the few muskets seen in the country appear to be chiefly employed in salutes. Of military tactics they are entirely ignorant; but courage, fortitude, and love of their country, have hitherto sufficed to preserve their independence, and to repel more than one foreign invasion of their territories.

Revenues.

The revenues yielded by the different provinces are stated to amount to 2834 tons of gold, or (at £10,000 sterling per ton), to £28,340,000 sterling. The emperor, however, only benefits by the revenue of the five provinces of his own fief or government. But, as before mentioned, he is entitled to two thirds of each mine that is opened; and he is said to possess a large treasure, disposed in chests containing each 1000 taels.

Political relations.

From the genius of their government, and jealousy of foreign interference, it does not appear that the Japanese have any external political relations. Their most natural allies would be the Chinese; yet it is certain that they do not treat even the Chinese merchants, who frequent the harbour of Nangasaky, with much ceremony and respect; and the Dutch at Japan seem to be reconciled to mortification, without gaining any adequate compensation by traffic.

Commercial relations.

Though these last have been established at Japan about two centuries, their trade has declined, instead of having increased; and as we have no right to infer want of vigilance on the part of the Dutch in watching over their commercial interests, we must suppose, either that they have nothing to offer the Japanese worth their acceptance, or that these latter are not to be seduced, by any means, to make an inconsiderate surrender, or depart from their maxims of state. When we reflect how often the independence of nations is sacrificed to commercial toleration, we must give the Japanese rulers credit for great prudence in their councils.

Dutch commerce.

The chief articles which the Dutch carry to Japan are bullion, European cloths, silks, spices, printed linens, sugar, sapan wood, tin, ivory, tortoise-shell, horns of the sea unicorn, which last is highly valued by the Japanese as a medicine. But, as before stated, they are restricted to the dispatch of two ships annually from Batavia. The cargoes of 13 ships between 1784 and 1793 inclusive, amounted to 3,534,521 florins. The returns made from Batavia to Japan during the same period, which consisted principally of copper and camphor, amounted to 2,764,879 florins.

Chinese commerce.

The Chinese send annually 12 ships from Ningpo, (or Simfo, as it is called by the Japanese,) five of which arrive in June and sail in October; the other seven arrive in December, and sail in March or April. They import chiefly sugar, ivory, tin plates, lead, silk stuffs, &c. They export copper, camphor, japanned wares, gold thread, buffalo horns, sowaas (an artificial metal) painted and coloured paper, umbrellas, and particularly the dye-fish, used as a medicine in China. Besides these, a kind of sea plant, and large dried mussels, called *awaby*, considered a great delicacy. Each Chinese vessel, or junk, being about equal to a ship of 400 tons, it would appear that their cargoes must be very considerable; yet Krusenstern remarks, that two ships of

500 tons each might stow away what is conveyed in all the twelve.

Historical epochs.

Kæmpfer has divided the Japanese history into three epochs, the fabulous, the doubtful, and the certain. The first reaching beyond the Mosaic æra of the creation, our acquaintance with it must be particularly unprofitable. The second, being mixed with Chinese history, and from the admission of Chinese symbols, demonstrates that Japan, in the earlier stages of society, was connected with China, and tends to fix a common origin. The certain period begins with the hereditary succession of the Dairis from 660 years before the Christian æra, to the year of our Lord 1585. In the reign of Gonda, the 90th Dairi, Japan was menaced by a great invasion from the Monguls, the invading fleet and army, amounting to 240,000 men, being dispersed and almost annihilated by a furious tempest, the Japanese piously ascribed their deliverance to the interposition of the gods. In 1585, the generals of the crown, or Kubos, assumed the supreme power, and these continue to reign uncontrolled, the Dairi having his separate court at Miaco, and presiding over the religious and literary concerns of the empire.

Account of Russian embassy.

We shall present our readers with some account, (for which we are indebted to Krusenstern,) of the reception of the Russian embassy by the Japanese; this relation may serve both to amuse the reader, and to illustrate the national character. Notwithstanding the national character for jealousy of the arrival of strangers on its coast, yet the Russian ambassador seems to have expected a favourable result to his mission. From the extent and contiguity of the Russian dominions, his excellency seems to have flattered himself that the offer and assurance of friendship of a powerful monarch would meet with a distinguished reception. But we cannot blame the policy which viewed with jealousy and distrust, the interference of so formidable a power as Russia in commercial pursuits. Whatever the arguments and motives of the Japanese politicians were, the Russian mission failed completely in its object, and even the permission formerly obtained, of sending a ship annually to Nangasaky, was recalled. Krusenstern is pretty liberal of abuse and sarcasm on the closeness of Dutch policy at Japan. It was not to be expected that the Dutch would favour the views of the Russian ambassador, or assist in opening a door of commercial competition to his nation. His excellency the councillor of state and chamberlain Resanoff, the Russian ambassador, and an adequate suite, arrived in the ship Nadeshda, in the harbour of Nangasaky, in October 1804. On the arrival of the Nadeshda, the first step resorted to by the Japanese, was the depriving the ship of its powder and fire arms, even to the officer's fowling-pieces. This measure was defended on the principle of national etiquette, the subjects of a foreign power not being allowed to go about armed in his Japanese majesty's dominions. But whatever the mortification and feelings of the ambassador were, their situation appears to have been particularly irksome to Krusenstern and his crew. At first they were prohibited from going ashore, and even from rowing about.

At length, after six weeks negociation, and on the plea of the ambassador's health, a spot was assigned as a walk, not exceeding 100 paces in length and 40 in breadth, in the immediate vicinity of which were two watch-towers. A debarkation of a single boat was attended by a fleet of 10 or 15 vessels surrounding it; in the same manner the boat was escorted back to the ship. So strict were the Japanese, that the Nadeshda was debarred intercourse with the Dutch ships, and letters were not even allowed to be sent by them to Batavia. The ambassador alone was permitted to transmit a report to the Emperor of Russia, translated by the interpreters into Dutch with such scrupulous accuracy, that every line of the translation terminated with the same letter as the lines of the original. This copy was deposited with the governor. On the departure of two Dutch vessels, Krusenstern having wished the captains a happy voyage, and made enquiries after their health, received in reply a sign with their speaking trumpet. For this silence, the chief of the Dutch factory apologised by letter to the ambassador, on the grounds that the captains had been forbidden to utter a word. Here our author breaks forth into a violent philippic against the Dutch, for their mean and servile compliance with Japanese prejudices, yielded in the true spirit of gain; and though Krusenstern may write under the influence of pique, we do not dissent from the justice of his observation, that such conduct is unworthy of the character of an enlightened and great nation. The important point being at length settled, of the ambassador having permission to land, a considerable building called Megasaky, was appointed for his residence, and watched with as much care as the seven towers of Constantinople. The situation of his excellency's quarters appears to have been selected with a remarkable regard to security. The building was placed on a neck of land, so near the sea, that at high water the tide came close to the walls. The windows were armed with double lattice-work, and consisted of spaces about a foot wide, calculated to admit a very moderate allowance of light. The whole habitation was secured by a bamboo fence, even on the sea side, the waves being deemed but an insufficient barrier by the Japanese. Large gates, with double locks, at which were stationed porters to take charge of the keys, and who seem to have executed their trust with troublesome fidelity, were placed on the land and sea sides. Besides, guards watched the spot, who did not slumber on their posts. Though our author expatiates on this barbarous intolerance of the Japanese, yet he does them the justice to admit, that such materials as he required for the repair of the ship were readily granted. The supply of provisions was also liberal to the ship's company. The landing of the Russian ambassador on the 17th December, was attended with circumstances of considerable pomp and ceremony. The Prince of Fisen's boat, a barge surpassing in size and magnificence every thing of the sort, (being 120 feet long,) was destined for the reception of his excellency. The walls and ceilings of the numerous cabins were varnished in the handsomest manner, and the stairs of red wood so highly polished, as to have the appearance of lacquer. On the decks were spread mats and the most costly carpets; and the whole boat was hung round with double rows of various coloured silk. On the ambassador stepping on board, the Russian imperial standard waved with the flag of the Prince of Fisen, whose guard took their station close to the standard. The Japanese fortresses were decorated with new flags and curtains, and manned by troops in their best dress. An innumerable fleet of boats accompanied the ambassador to the town of Nangasaky. So far his excellency was ushered into his Japanese majesty's dominions in a manner suitable to the representative of a powerful monarch. But he had no sooner landed and entered into his dwelling, than he was locked up like a state criminal, and the keys were sent to the governor. The day

Account of Russian embassy.

after the ambassador left the ship, two Banjos, accompanied with a great number of boats, come on board to receive the presents. Two boats lashed together, with a platform of strong planks laid across, covered with red cloth, was appointed to receive the large mirror. All attempts to persuade them to remove this valuable covering were ineffectual, as the respect with which every thing was attended destined as a present to the emperor, required to be scrupulously enforced, and rejected all paltry consideration of economy. A guard instantly jumped into the boat for the honour of the mirror. One of the interpreters being asked how it would reach Jeddo, replied, it would be carried there. An objection being raised on the ground of the distance and number of men required to carry it, the interpreter gravely answered, that nothing was impossible to the emperor of Japan; and that a live elephant, a present from the emperor of China, had been so transported. We are furnished with another trait of Japanese character by the same author, which shews with what exactness the emperor's orders are executed. A Chinese junk was driven ashore on the east coast of Japan in a gale of wind, and lost her masts and rudder. According to an ancient regulation, every ship touching on the Japanese coast, by whatever accident, must be brought to Nangasaky. Accordingly this junk must find its way there. This could only be effected by a process of towing; and the great probability was, that during the voyage, which lasted 14 months, the towing-fleet, consisting of 100 boats and 600 men, with the said junk, would all go to the bottom. But neither the intricacy of the navigation, nor perils by storm frequent on this coast, nor the length of the voyage, nor the inadequate compensation of so much toil by the object being attained, weighed for a moment, when placed in competition with established custom and the emperor's orders. On the 19th February 1805, the Russian ambassador received intimation that the emperor of Japan had sent a person, attended by eight nobles, with full powers to treat with him. The person deputed was said to be of the highest rank, and one who was permitted to view the emperor's feet, though not to elevate his look higher.

The Japanese plenipotentiary having arrived, much altercation took place on both sides in adjusting the ceremonies to be observed at the audience. It was settled that the ambassador should pay the plenipotentiary an European, and not a Japanese compliment. This last is said to be so very degrading, that not even the lowest European would submit to it. The ambassador, however, was to appear without his sword or shoes, nor would they allow him a chair, or any kind of European seat. He was to sit with his feet tucked under him, in front of the governor and plenipotentiary. A norimon, or sedan chair, was allowed the ambassador, but the officers of his suite were to walk. The arrangements being finally made, the 4th of April was appointed for his first audience. The ambassador and his suite, consisting of five persons, and a serjeant to carry the standard of Russia, were conveyed in a barge adorned with flags and curtains, and landed at a place called Mussul Trapp. On an occasion, for which such preparations were made, and expectation raised, merely an exchange of compliments took place, and a few insignificant questions were put. The second audience was of the same nature, and here ended the matter. An order was delivered to the ambassador, prohibiting any Russian ship from again visiting Japan. The presents, and even the letters from the Emperor of Russia, were refused. It was enjoined that any Japanese cast upon the coast of Russia, should be delivered over to the Dutch, who would send them by way of Batavia to Nangasaky. Finally, the Russians were prohibited from offering presents and making purchases, and from visiting or receiving the visits of the Dutch factor. The repair of the ship, and the supply of provisions, were declared to be taken into the imperial account. And it was notified, that the Emperor of Japan had sent 2000 sacks of salt, and 100 of rice, besides 2000 pieces of cassock or silk wadding, the former as a present for the crew, and the latter for the officers. The reason assigned for refusing the presents was, that the Emperor of Japan would be obliged to make a suitable return to the Emperor of Russia, and to send an ambassador to St Petersburgh; and that it was contrary to the laws of the empire for any Japanese to quit his country. Such was the result of an embassy, of which such sanguine hopes had been formed in Russia. Not only were no new advantages gained, but the written permission granted to the Russians to visit Nangasaky was revoked. All communication is now suspended between Russia and Japan, nor is it expected that it will be again opened until some great change takes place in the Japanese government. Nor, perhaps, is such a change very remote. At the very moment of our writing this article, we find it mentioned, among continental intelligence, that the Dairi of Japan has been intriguing in secular affairs, and endeavouring, by means of his priests and adherents, to gain the people to his cause. Whence the supremacy of the Kubo is threatened, and a popular insurrection apprehended.

Latest accounts from Japan.

The Ainos described by Krusenstern.

We shall conclude this article, by offering to our readers a description, from Krusenstern, of the Ainos, a race of people but little known in Europe. As this author's account has simplicity of narrative, and the appearance of truth to recommend it, we shall make no apology to our readers for presenting it in his own words. We shall only premise, that the island of Jesso was wrested from the Ainos, its original inhabitants, by the Japanese; the former are now confined to a small space, which alone retains the name of Jesso, the rest of the island being called Matzumary, from the principal Japanese settlement here. The Japanese discipline exists in full force in the most northerly part of the island, the farthest limit of their empire.

Island of Jesso.

"The Ainos," Krusenstern observes, "are rather below the middle stature, being at the most five feet two or four inches high, of a dark, nearly black, complexion, with a thick bushy beard, black rough hair hanging straight down, and excepting in the beard, they have the appearance of the Kamtchadales, only that their countenance is much more regular. The women are sufficiently ugly: their colour, which is equally dark, their coal black hair combed over their faces, blue painted lips, and tattooed hands, added to no remarkable cleanliness in their clothing, do not give them any great pretensions to loveliness; this at least was the case with those we had an opportunity of seeing on the north side of Jesso. We perceived, indeed, in Aniwa bay, some who were younger, whose eyes had not lost their brightness, and who on this account were not quite so ugly: but I confess that the impression even these made upon me was equally unfavourable. They are modest however in the highest degree, and in this point form the completest contrast with the women of Nukahiwa and of Otaheite. Their modesty even amounted to bashfulness, occasioned perhaps by the jealousy of their

Japan.
Account of the Ainos.

husbands, and the watchfulness of their parents: they never quitted for a moment, while we were on shore, the huts in which they had assembled, and were extremely distressed when Dr Telesius made drawings of them.

The characteristic quality of an Aino is goodness of heart, which is expressed in the strongest manner in his countenance; and so far as we were enabled to observe their actions, they fully answered this expression. These, as well as their looks, evinced something simple, but noble. Avarice, or rather rapacity, the common fault of all the wild inhabitants of the southern islands in the eastern ocean, they are entirely strangers to: in Romanzoff bay they brought fish on board, which they immediately left to us, without demanding the least thing in return; and much as they were delighted with the presents made to them, they would not admit them as their property, until they had been frequently assured by signs of their being intended for them.

"The dress of the Ainos consists chiefly of the skins of tame dogs and seals; but I have seen some in a very different attire, which resembled the parkis of the Kamtschadales, and is, properly speaking, a white shirt worn over their other clothes. In Aniwa bay they were all clad in furs; their boots were made of seal skins, and in these likewise the women were invariably clothed. In Romanzoff bay, on the contrary, we saw only two fur dresses, one of which was a bear's skin, the other made of dogs' skins; and the rest of the people were dressed in a coarse yellow stuff, made of the bark of a tree, (as we ascertained in their houses,) which a few wore, bordered with blue cloth. Under this dress they had another of a fine cotton stuff, that they probably purchase of the Japanese. Here we saw no boots such as were worn by every one in Aniwa bay; but, instead of them, they used Japanese straw slippers. A few of them covered their legs with a kind of half stockings stitched together, of the same coarse stuff as their upper garments. This difference in the dress of the Ainos of Jesso and Sachalin seems to prove a much greater degree of wealth in the latter island, and the men here appeared to wear a more cheerful aspect; but whether this is owing to their superior wealth in fish and furs, which find a certain market with the Japanese, or to their little dependence on these latter, I cannot pretend to decide, though I am inclined to believe the former. The greatest part of them went with their heads uncovered; others wore a straw hat, pointed in the middle. I fancy it is not the custom of the country to shave the hair, though I saw several of them with their heads half shorn, probably only in imitation of the Japanese. The women, even the youngest, use no ornaments on their heads; but, as I have already mentioned, they invariably paint their lips blue,—a practice which, to an European accustomed to the rose colour, appears extremely ugly. On the contrary, many of the male sex wore ear-rings, which were commonly merely a brass ring. I purchased a pair off a young man, made of silver, with large false pearls suspended from them. The possessor seemed to set great value on these ornaments, being very unwilling to part with them; and twice he repented of his bargain, took them back again, and demanded a higher price. An old coat, two cotton cloths, and a piece of flat white metal, were the treasures for which he at last exchanged them. Buttons and old clothes were the articles the Ainos most sought after, and for which they gave their pipes and other trifles.

"The huts we saw in Aniwa bay were, as I have already said, probably newly built, and served only for their summer residence. In Romanzoff bay they appeared to be their constant abode both in winter and summer. The two we visited, and near to which were balagans for drying fish, consisted of a single large room, which, with a small division at one end, occupied the whole interior of the house. Their construction did not seem to me to be very solid, and, unless the houses are entirely covered with snow, as in Kamtschatka, I cannot conceive how they are able to bear the cold, which must be intense here in the winter; since, even in the month of May, the thermometer only shewed three degrees of warmth. In the middle of the room was a large hearth, around which the whole family, consisting of eight or ten persons, was seated. The furniture consisted of a large bed, over which a Japanese mat was spread, and several boxes and barrels. All their utensils were of Japanese manufacture, and mostly lacquered. It appeared, from the interior of the house, that the inhabitants possessed a degree of affluence such as is not found among the Kamtschadales, still less among the Aleuti, and the unfortunate inhabitants of Kodiack. The great provision of dried fish bore indeed rather a disgusting appearance; but no objection can be taken to this when we reflect, that their existence depends upon them, fish being probably their only nourishment, and their houses on this account being chiefly scattered along the shore. We perceived no symptoms of cultivation, not even any plantations of vegetables; nor did we see any tame fowls or domestic animals except dogs, which they had in great abundance; and Lieutenant Golowatscheff found in Mordwinoff bay, on the west coast of Patience bay, above fifty in one place. In all probability they use them for their journeys in the winter; for we saw in Aniwa bay a sledge which bore a perfect resemblance to a Kamtschadale narte. Dog skins, also, are here an important article of dress. We were struck on perceiving, that snow-water was the common beverage of the people on the north side of Jesso, although that of the river, which flowed into the bay, was extremely good. Perhaps the fear of cold in the winter, as they would have to fetch their water from the river, which is not very near to their houses, has so accustomed them to snow-water, that they prefer it to that of the river so long as they are able to procure it. It seemed also the custom here, (at least, it was so in all the houses which either I or any of my officers visited,) to bring up a young bear in the house, to which a place was assigned in one of the corners of the room, and which was decidedly the most restless of any of its inhabitants. One of our officers was desirous of purchasing one of these bears, and offered his great-coat in exchange for it; but he could not persuade the proprietor, although cloth is of great value in the eyes of the Ainos, as the Japanese are unable to supply them with it, to part with his young elève.

"It would be presuming too much to enter into any detail upon the form of government and the religion of the Ainos, as our stay here was much too circumscribed for us to have instituted any inquiries into these subjects; but, with their limited population, it is not easy to imagine any other than a patriarchal constitution. During our visit to one of their houses in Romanzoff bay, we observed in the family, which consisted of ten persons, the happiest state of harmony, or rather a perfect equality. We continued there some hours, and were scarcely able to distinguish the head of the family, so little assuming were even the oldest towards its

Account of the Ainos.

youngest members. Accordingly, in dividing a few presents among them, I preserved a most perfect equality, which they all appeared pleased with, no one, not even the oldest, remarking, that I had given him too little in proportion to the others; on the contrary, they called my attention to a little girl, about eight years old, whom I had overlooked, and who now obtained her share. This unanimity, and the silence which reigns among them, awake the most favourable feelings towards them. Here was no loud talking, no immoderate laughter, and still less any disputing. The satisfaction that appeared in all their countenances as they spread the mats round the hearth for us; their readiness, when we were going away, to launch their canoes and carry us across the shallows to our boat, when they perceived that our boatmen were stripping themselves for this purpose: but still more than all this, their modesty never to demand any thing, and even to accept with hesitation whatever was offered to them, wherein they differ very much from the inhabitants of the west of Sachalin, whose diffidence La Perouse could not speak of with praise; all these uncommon qualities, for which they are not indebted to any polished education, but which are merely the marks of their natural character, make me consider the Ainos as the best of all the people that I have hitherto been acquainted with.

"I have already mentioned their inconsiderable numbers, particularly in Jesso. On the north of this island we counted only eight dwelling-houses, and if we admit ten as the number of each family, this makes that of the inhabitants of this district only eighty. Farther inland they probably have no establishments; for as their whole nourishment consists of fish, they only settle on the sea shores. In Salmon Bay, and Tamary Aniwa, the Ainos probably amount to three hundred; but we were there at the time of the fishery, and it is chiefly from hence that the Japanese procure this article, for which they are obliged to have recourse to the inhabitants of the neighbouring bays, who settle here at such times, in order to prepare so large a quantity. Not only the recently built houses of the Ainos in the vicinity of the Japanese factory is a proof of this, but also the number of houses provided with furniture but destitute of inhabitants in Mordwinoff Bay, where Lieut. Golowatscheff, who visited that part, found but a few persons, and these not merely to guard the property, for they seemed to consider it as their own.

"According to the most ancient accounts we have of this island, its inhabitants are said to be covered with hair. The Chinese describe it as a large country full of wild people, whose whole body is covered with hair, and with such enormous beards that they are forced to raise them up in order to drink. The Dutch in the well known expedition in 1643, under the command of Captain Vries, and the Russians under Spanberg in 1739, confirmed this description. Although so many concurring accounts seem to testify the fact of the natives of Jesso being overgrown with hair, nevertheless I am disposed, from our experience, to declare this report to be fabulous. The Jesuit Hieronymus de Angelis, the first European who, in 1620, visited Jesso, merely mentions their bushy beards, but says not a word of their hairy bodies; and as he resided for some time amongst them, he certainly had a better opportunity of examining their personal qualities than could be found in the short visits of the Dutch, the Russians, or the Chinese, and he would not have failed to make known so striking a circumstance. On the north of Jesso we examined some people, but found that, except their bushy beard and the hair on their faces, there was not the least thing to give probability to such a story. In Aniwa I got several of them to uncover their breasts, arms, and legs, and we were here convinced to a certainty that the greater part of the Ainos have no more hair upon their bodies than is to be found upon those of many Europeans. Lieut. Golowatscheff found indeed in Mordwinoff Bay a child of eight years old, whose body was entirely covered with hair; but he immediately examined its parents and several other grown up persons, and found them all in that respect like Europeans. I will not flatly contradict the report of older and modern navigators, whose credibility I do not argue against; but I believe that they have exaggerated this story respecting the Ainos, or, what is the same thing, the natives of the southern Kuriles: at least it is not equally true with regard to all. Perhaps the impression which the Dutch received from their bushy beard, hairy face, and lank locks, added to the uncleanliness of their persons, left an idea that their bodies must be as much covered as their faces; and as they did not wait to examine whether this were really the case, this gave rise to a story which has been ever since repeated as a fact."

The following notices respecting Japan, communicated in a discourse to the Literary and Scientific Society at Java by the Honourable Governor Raffles, and drawn from the information of Dr Ainslie, who had resided four months in Nangasaki, may be considered as the most recent intelligence on the subject of this article.

Recent account of the Japanese by Dr Ainslie.

Every information obtained by that gentleman tends to confirm the accuracy, ability, and impartiality of Kæmpfer, whose account of Japan is represented as one of the most complete works of the kind that was ever produced in the same circumstances. The Japanese acknowledge that from this book they know their own country; and their first enquiry to the English commissioners was for a copy of Kæmpfer. In expressing the estimation in which his writings were held among them, they literally observed, that "he had drawn out their heart from them, and laid it palpitating before us, with all the movements of their government, and the actions of their men!" The natives are represented by Dr Ainslie as a nervous, vigorous people, whose bodily and mental powers assimilate much nearer to those of Europe, than what are usually attributed to Asiatics; as possessed of masculine features perfectly European, except the small lengthened Tartar eye, which almost universally prevails; as perfectly fair and even blooming in their complexion; and actually exhibiting among females of the higher class more of the hue of health than is usually found in Europe. He describes their proficiency in the sciences, especially in metaphysics and judicial astrology, as sufficient to evince a vigorous intellect; and their skill in the arts as by no means resembling the stationary mediocrity of the Chinese, but as the effect of an ardent and progressive principle of improvement. Nothing, he tells us, is so offensive to the feelings of a Japanese, as to be compared, in any one respect, with the Chinese; and the only occasion on which he ever saw the habitual politeness of a native surprised into a burst of passion, was when, upon a similarity between the two nations being unguardedly asserted, the latter laid his hand upon his sword. They have at least none of that uniformity of character which the artificial system of government has produced in China; and their women particularly, associate among themselves like the ladies of Europe. Dr Ainslie was present at frequent entertainments among the natives; and on one of these occasions particularly, a lady from the court of Jeddo performed the honours of the table with an ease, elegance, and address, that would have graced a Parisian. The usual dress of the Japanese women, even of the middle rank, is remarkably costly; and its value might supply the wardrobe of an European lady of the same rank for twenty years. The Japanese, with an apparent coldness, derived from that system of espionage and principle of disunion dictated by the government, are eager for novelty, and warm in their attachments, strongly inclined to foreign intercourse, notwithstanding the prohibitory political institutions of their country, and apparently ready to throw themselves into the hands of any nation of superior intelligence; but at the same time full of contempt for every thing below their own standard of morals and habits. The failure of the embassy from Russia in 1814, which might seem to contradict this remark, Dr Ainslie considers as attributable to particular circumstances, which however are not sufficiently detailed, but are intimated as originating in the influence of the interested competitor at the head of the Dutch establishment. The warehouse in which the Russian mission had been lodged was pointed out to Dr Ainslie, who observes, that, "as the rats were let out, the count and his suite were let in, where they remained for six long months with scarce room to turn; the mark of obloquy to the Japanese, and the laughing stock of the European factory." So lively was the impression of the occurrence, that the chief Japanese officer asked the English commissioner, "if he too would condescend to play the part of the Russian count?"—the officer answering to his own question, "No, I trust not." Even the illiberality of the Japanese on the subject of religion, is affirmed by no means to correspond with the representations hitherto made of their character; and the annual test of trampling on crucifixes and other Catholic images, is said to be denied and derided as a foolish story by the native priests. Upon visiting the great temple on the hills of Nangasaky, the English commissioner was received with marked respect, and sumptuously entertained by the patriarch of the northern provinces, a man eighty years of age; and when one of the English officers present heedlessly exclaimed in surprise, Jasus Christus! the patriarch, turning half round with a placid smile, bowed significantly, expressive of a hint to avoid that subject in that place, and took leave with a hearty shake of the hand. It is mentioned as an extraordinary fact, that, for seven years past, since the visit of Captain Pellew, notwithstanding the determination of the court not to enter into foreign commerce, the English language has, in obedience to an edict of the Emperor, been cultivated with considerable success by the younger members of the college of interpreters, who were found very eager in their inquiries after English books. While the commissioner was at Nangasaky, there arrived a large detachment of officers of rank, who had been employed nearly four years in making an actual survey of every foot of the empire and the dependent isles, one fourth part of which they had not yet completed. The survey appeared to be conducted on a scientific principle, to be most minute and accurate in its execution, and to have for its object the completion of a regular geographical and statistical description of the country. The Japanese, in short, are wonderfully inquisitive in all points of science, and are anxious to receive information, without inquiring from what quarter it comes; and, in the opinion of Dr Ainslie, are a people with whom the European world might hold intercourse without compromise of character. The result of all that the commissioners observed, is said to be an impression on the minds of those who are most competent both to judge and act in the matter, that a commercial intercourse between Great Britain and Japan might easily be opened. See Kæmpfer's *History of Japan;* Thunberg's *Travels*, vols. iii. and iv; Krusenstern's *Voyage round the World;* and the *Transactions of the Literary and Scientific Society at Java.*

JAPANNING, is a mode of ornamenting various articles with a hard varnish, which bears a good polish, and can be made of brilliant colours and ornaments.

The natives of Japan and China practise this art in great perfection. They have a decided advantage over the European japanner in their materials. They use a kind of resin called lac, which is the sap or juice of a tree. The Japanese make incisions in the lower part of the trunk, and receive the lac, which flows in pots set beneath the incisions; this lac is at first of the colour and consistence of cream, but it becomes black on the surface when it is exposed to the air. The whole mass is required to become black before it is used, and for this purpose it is put into very shallow bowls, and continually stirred with an iron rod during twenty-four hours, so as to expose every part to the action of the air; this makes it thicker than before, and of a fine black colour, which they heighten by adding powdered charcoal.

When this lac is laid on the work, and dried, it is polished with a stone and water, and the polished surface is ornamented by gilding or painting, which is secured by an external coat of varnish, made of oil and turpentine, boiled to a proper consistence.

The japanning among Europeans is differently performed, but the work bears a near resemblance to that of the Japanese when finished; it is applied to wood, papier-maché, leather and iron, or tinned iron. When the articles are of that nature, that they will not bear heating in a stove to dry and harden the japan, they must be done with lac similar to the real japan; but as the lac is only brought to Europe in a solid form, it must first be reduced to a fluid state, by dissolving it in alcohol, or some essential oil; and this varnish being spread on the work, the alcohol or oil will evaporate, and leave a hard superficial coat of lac. The varnish may be mixed with the requisite colours, or the colours may be painted upon the surface of the varnish, between the successive coats which are applied; and in the latter case admit of painting according to a design.

For such goods as will admit of sufficient heat in a stove, a more economical method is pursued, the principal coats of japan being made of boiled linseed oil, with proper colouring matters. These are dried and hardened in the stove, and the painting or gilding is laid on; a thin lac varnish is lastly applied, to give the external surface; but it assimilates so well with the first coats of japan, that the whole wears as well as if it was done with solid lac in the Japanese method.

Japanning with lac.

Japanning with lac. This is principally used for ornamenting wood, leather, and paper, but the latter can be japanned by heat like the metals.

The following receipts are given in the Handmaid to the Arts, for the varnishes which are to form the grounds or surfaces on which the painting or gilding are to be laid. Dissolve two ounces of coarse seed lac, and two ounces of resin, in one pint of rectified spirits of wine. This varnish must be laid on in a warm place; and the work will be better done if the substance to be japanned can be warmed also, but all moisture and dampness must be carefully avoided. Two or three coats of this coarse varnish must be applied, preparatory to laying the grounds, which contain the colour, and which are made as follows.

For a white ground.

For a white ground, prepare flake white, or white lead, by washing it with water, and then by grinding it with one-sixth of its weight of starch; when this is dried, temper it properly for spreading, with mastic varnish, which is prepared by dissolving mastic in spirits of turpentine, by a gentle heat in a water bath; or the colour may be compounded with gum anime, reduced to powder, and ground first with turpentine, and then ground with the colours, adding as much of the mastic varnish as is necessary to make it work with the pencil. When this white japan is laid on, the external varnish which is applied upon it after the painting or ornaments are finished, must be of the most transparent nature, that it may not injure the whiteness of the colour. For this purpose select the clearest and whitest grains from a large parcel of seed lac, reserving the coarser grains for other varnishes; take two ounces of this chosen lac, and three ounces of gum anime, reduce them to a gross powder, and dissolve them in a quart of spirits of wine; five or six coats of this varnish must be laid on over the white colour. The seed-lac will give a slight tinge to the colour, but the hardest varnish cannot be made without it; when hardness is not so essential, a less proportion of seed-lac may be used, and to take away the brittleness of the gum anime, a small quantity of crude turpentine may be added. Another varnish, either for mixing up with the white colours, or for covering them when laid on, is made of gum anime, dissolved in old nut or poppy oil, by gently boiling the oil, and putting into it as much of the gum as it will take up. This varnish must be diluted with oil of turpentine for use; it will not bear polishing, and must therefore be applied very carefully to lay it smooth.

For blue japan grounds.

For blue japan grounds, use a bright Prussian blue, or smalt, or verditer, glazed over by Prussian blue; the colours are best mixed with shell lac varnish, and brought to a polishing state by five or six coats of seed lac varnish. If the blue ground is bright, and the shell lac varnish is laid on, it will give a green hue, owing to its own yellow colour; the varnish of oil and gum anime, as above, being used for the external varnish, will have a clearer colour, but it is not so hard.

For red japan grounds.

For red japan grounds vermilion may be used to produce a scarlet ground, but it has a glaring effect when used alone. This will be in some measure corrected by glazing it over with carmine, or fine lake, or even with rose-pink. For a very bright crimson, instead of glazing with carmine, Indian lake should be used; the lake may be dissolved in the spirit of which the varnish is composed, and a coat of this being laid on, the shell lac varnish may be used to produce the external surface, as it will very well transmit the tinge of the Indian lake.

For yellow japan grounds.

For yellow japan grounds, for bright yellow, king's yellow or turbeth mineral should be employed, either alone or mixed with fine Dutch pink. The effect may be heightened by dissolving powdered turmeric root in the alcohol, which is used for making the external varnish. The alcohol should be strained off from the dregs of the turmeric, before the seed lac is put in to form the varnish. Dutch pink alone, if of the best quality, will make a good yellow ground.

For green japan grounds.

For green japan grounds, king's yellow and bright Prussian blue may be mixed to make a green, or turbeth mineral and Prussian blue; and a common kind may be made of verdigris, mixed with either of the above yellows, or with Dutch pink. For a very bright green, the crystals of verdigris, called the distilled verdigris, should be employed; and to heighten the effect, the colour should be laid on a ground of leaf-gold, which renders it very brilliant.

For orange japan grounds.

For orange japan grounds, mix vermilion or red lead with king's yellow, or Dutch pink, or orange lake used alone is a fine colour. To prepare this, take of the best annotto four ounces, and of pearl ashes one pound; put them together into a gallon of water, and boil them for half an hour, then strain the solution through paper. Make also another solution of a pound and a half of alum, in a gallon of water, and mix this gradually with the solution of pearl ashes and annotto; a precipitate of the colouring matter will be formed, which being dried in cakes or lozenges, is the orange lake.

For purple japan grounds.

For purple japan grounds, a mixture of lake and Prussian blue may be used, or vermilion and Prussian blue for a coarser purple.

For a black japan ground.

For a black japan ground. Ivory black and lamp black are the proper materials for this purpose. They should be laid on with shell lac varnish, and the external varnish may be of seed lac, as the tinge of it can do no injury.

For a ground of gold.

For a ground of gold. Gold leaf may be laid on over the whole surface. See *Japanners* GILDING. Or the imitative gold or silver powder may be used with the size there described. When the desired ground is obtained, the ornamental painting is next performed. The colours for painting are mixed up with varnish of shell or seed lac, dissolved in spirits of wine, or otherwise by varnish of mastic, dissolved in oil of turpentine; to which gum anime may be added, as before directed, for mixing up the colours of the white ground, and which applies to all the other grounds. There is, in fact, no difference between the manner of preparing the colours for laying the grounds, or for painting upon the ground. The pencils must be moistened either with the spirits of wine or oil of turpentine, so as to make the colours work. In some very nice works, the colours may be tempered in oil, for the more free use of the pencil, and to obtain greater dispatch. The oil should previously have one-fourth part of its weight of gum anime dissolved in it, or gum sandarac or mastic. When this oil is used, it should be diluted with spirit of turpentine, that the colours may lie more even and thin.

When the painting is to be on a ground of gold, water colours may be used for the ornamental painting. They are prepared with isinglass size, corrected with honey or sugarcandy. The ornamental gilding for japanners work is explained in the article GILDING.

External varnish.

External varnish. The hardest varnish is made of seed lac, as before mentioned, but has a yellow tinge. To make this, wash the seed lac in water to clean it from impurities; dry it, and powder it coarsely; then put three ounces of it into a bottle with a pint of rectified spirits of wine. The bottle should not be above two-thirds filled, and must be gently heated, and shaken frequently, until as much of the lac is dissolved as can be, and the varnish is then to be poured off into a bottle, and kept stopped very close. The more highly rectified the spirit is, the more lac it will dissolve. This varnish must be laid on in a dry warm place, and the work previously made perfectly dry: no part should be crossed or passed twice over in laying the same coat, if it can be avoided.

When the outer varnish has been as often repeated as is necessary, the work is polished with a rag dipped in fine powdered pumice stone, or rotten stone; and when a good surface is thus obtained, it is finished by rubbing it with the hand alone, or with butter or oil.

About the middle of the last century, almost all elegant furniture was japanned by these means; but it is now disused, except for coaches, and for some small articles. The japanning of such articles as will bear the heat of a stove, to harden the varnish, is now brought to a very high perfection, and is very cheap compared with the lac japan.

Japanning of tin and paper wares by the stove.

Clear japan varnish.

Japanning of tin and paper wares by the stove. This is distinguished into two kinds; clear work, in which the japan is required to be transparent; and black japan, which is opake. The *varnish for clear work* is composed of raw linseed oil, umber, and a little amber, with a small portion of white rosin. These materials are boiled for several hours in a cast-iron pot, which is set in brickwork over a furnace, and the mouth of the pot surrounded by a funnel or chimney of brickwork, with only one opening to obtain access to it; and this opening is provided with an iron door to shut close in case the materials should take fire. The boiling evaporates the most fluid parts of the oil, and the varnish becomes thick. It is known to be sufficiently boiled by letting fall a drop on a piece of tinplate; and if it does not spread upon the surface, but keeps in a circumscribed spot, the varnish is esteemed sufficiently boiled, and may be taken out of the boiler. This varnish is to be mixed up to a proper consistence for working with spirit of turpentine, the varnish being a little warm.

Black japan varnish.

The black japan varnish is made by the same process, but asphaltum is used instead of amber; and it is thinned for use with tar spirit instead of spirit of turpentine; also lamp black is added to the varnish.

Either of these varnishes are to be laid upon the work by a soft hog's hair brush, such as is known by the name of a painter's tool, and it must be prepared by drawing out all the hairs which are thicker than the others, or all those which have the flesh end downwards. The work must be carefully cleaned from dirt, resin, &c. and with this brush it is thinly coated over with the varnish. It is left for a few minutes to set, and it is then put into the drying stove, the heat of which at first makes the varnish more fluid, and it flows with great evenness over all the surface; but when the spirits evaporate, the varnish becomes solid, and in thirty or forty minutes may be taken out, and suffered to cool previous to varnishing again. The proper time for the second application, is known by applying the finger on the varnished surface with a moderate pressure; if the adhesion of the varnish is such that the finger will not slide over the surface, at the same time that there is no actual sticking to the finger, it is then in the right state to receive another coat of varnish. The work should not be suffered to dry beyond this state, otherwise the successive coats will not adhere so firmly. A second varnish being applied, the article is dried again; then a third coat is applied, and the work is left in the stove five or six hours, or all night, to harden and dry off the varnish. If it is the clear varnish which is thus treated, this time will be sufficient; but it will grow darker in proportion as it is longer exposed to the heat, or as the heat is increased. For black work the heat is raised as high as possible, without melting the soldering, or charring the varnish; and this is continued three or four days. This process makes the hardest and most durable of all varnishes, and of a most brilliant jet black colour.

To obtain a smooth surface, it is rubbed with woollen rag with pumice stone powder and water, and it is polished by rottenstone powder, and finished by the friction of the bare hand with a little butter.

Mottled japan, in imitation of tortoise shell.

Mottled japan in imitation of tortoise shell. This is done by covering the tin with one coat of varnish as above, mixed with Venetian red, and then it is coated with black varnish. The fingers are drawn over the varnished surface in a waving direction, to distribute the varnish unequally, and thus cause the red colour to be shewn through in spots or clouds, imitating tortoise shell. Otherwise the tin is painted in spots with vermilion mixed in shell lac varnish; and this is coated with the clear varnish, which is afterwards stoved till it becomes deeply coloured, and is rather opake, so that it shews the vermilion spots and the surface of the tin beneath in an imperfect manner, and much resembles the clouds of tortoise shell.

Some simple articles in wood may be treated in this way, provided they are not put together in pieces with glue, and are not liable to be split by the heat; for instance, walking canes are most beautifully ornamented at Birmingham. These processes of japanning by heat are to be found in some receipts by Kunkel, but do not appear to have been practised till the Birmingham manufacture was begun.

When ornamental painting or gilding is required, it is done upon a clear japan ground when the same is set. A layer of gold size being spread over the surface, (see GILDING,) the leaf gold or gold powder is applied, and also the required painting, the colours being mixed as before directed for lac japanning. Stencils are sometimes used to lay the gold powder in particular patterns: they are pieces of paper with openings cut out in particular forms; and being applied upon the surface of the work, if the powder is applied by a piece of rag it will be laid according to the pattern cut out. A variety of different coloured metallic bronze powders are used in the Birmingham ware; and for the smaller parts they lay them on with stump brushes.

Transparent or Pont-y-pool japan.

Transparent or *Pont-y-pool Japan.*—The articles japanned in this way are prepared by a good ground of black varnish made very smooth; a layer of gold size is then laid on, and the whole surface is covered with silver powder; upon this is laid a coat of thin varnish mixed with the desired colour, such as Prussian blue, or lake mixed with spirit of turpentine, to make it spread. When this is dry, it is sized over, and painted or ornamented with gilding in silver leaf or powder. The whole is coated with an external varnish of a gold colour, which changes the colour of the silver leaf to that of gold.

The use of the first coat of silver powder is to give a resplendency to the colour, which is very beautiful.

The French have a mode of producing flowered stains of colour of the most brilliant hues, which are waved very much like the flowers which are found in a frosty morning upon the windows of an apartment. We are informed that it is done by means of an acid applied to the surface of the tin before it is japanned.

The stoves for japanning are built of brick or stone, generally three stories high, with three stoves upon each floor. The fire is at the bottom, and is covered over with a strong iron plate. The flues are carried up at the sides and ends of the stoves, and are made to afford three different degrees of heat, for drying off the clear varnish, or for darkening it, or for darkening the black varnish. (J. F.)

JAVA.

Situation. JAVA,[*] the southernmost of the Sunda islands, is situated between 6° and 9° of south latitude, and between 105° and 115° of east longitude from Greenwich. It extends, nearly in the direction of east and west, about 650 miles, and its average breadth is about 95. On the north lies the island of Borneo; on the north-east, Celebes; on the east, the islands of Bali and Madura; on the south and west, the Indian ocean; and on the north-west, the island of Sumatra, from which it is separated by the Straits of Sunda, which, at the narrowest point, are about 20 miles broad. On entering these straits a fine prospect opens to the view. The low coast of Sumatra appears covered with trees, behind which its majestic mountains rise in gradual ascent; while the opposite coast of Java, not inferior in beauty, indicates the fertility of its soil, by its numerous rice fields, and groves of cocoa-nut and palm trees.

Description. The whole of the north coast of Java is low, swampy, and woody ground, except a little to the west of Bantam, where the high land stretches down to the sea-coast. On this side are several bays, where there is safe anchorage during the good or south-east monsoon; but in the bad monsoon, when the north-west wind blows hard, it is dangerous to anchor near the coast. The south coast is less known than the northern, and is a bold rocky shore almost inaccessible. A chain of high mountains, commencing at the eastern extremity, in the province of Balambouang, running to the westward, and gradually decreasing in height, divides the island longitudinally into two parts, of which the northern section is the largest and best.

Volcanoes. In several mountains of this great chain are observable the craters of volcanoes, which were formerly violent in their eruptions, and many of which still emit smoke after heavy rains. Numerous mineral springs of various virtues and temperatures, are found in their vicinity. An account of a very curious natural phenomenon in the plains of Grobogan, about 50 miles N. E. of Solo, has been published by Mr Brande, which may be deserving of notice in this place as a species of volcanic eruptions. As a party from Solo "approached the village of Kuhoo, they saw, between two trees in a plain, an appearance like the surf breaking over rocks, with a strong spray falling to leeward. The spot was completely surrounded by huts for the manufacture of salt. **Mud volcanoes.** Alighting, they went to the bludugs, as the Javanese call them, and found them to be on an elevated plain of mud, about two miles in circumference, in the centre of which immense bodies of salt mud were thrown up to the height of from ten to fifteen feet, in the form of large globes, which, bursting, emitted volumes of dense white smoke. These large globes or bubbles, of which there were two, continued throwing up and bursting seven or eight times in a minute by the watch. At times, they throw up two or three tons of mud. The party got to leeward of the smoke, and found it to smell like the washing of a gun-barrel. As the globes burst, they threw the mud out from the centre with a pretty loud noise, occasioned by the falling of the mud upon that which surrounded it, and of which the plain is composed. It was difficult and dangerous to approach the large globes or bubbles, as the ground was all a quagmire, except where the surface of the mud had become hardened by the sun. Upon this they approached cautiously to within fifty yards of the largest bubble, or mud pudding, as it might very properly be called; for it was of the consistency of a custard pudding, and of very considerable diameter. They also got close to a small globe or bubble, (the plain was full of them of different sizes,) and observed it closely for some time. It appeared to heave and swell; and when the internal air had raised it to some height, it burst, and the mud fell down in concentric circles, in which shape it remained quiet, until a sufficient quantity of air was again formed internally to raise and burst another bubble. This continued at intervals from about one half to two minutes. From various other parts of the quagmire, round the large globes or bubbles, there were occasionally small quantities of mud shot up like rockets to the height of 20 or 30 feet, and accompanied by smoke. This was in parts where the mud was of too stiff a consistency to rise in globes or bubbles. The mud, at all the places they came near, was cold on the surface; but they were told it was warm beneath. The water which drains from the mud is collected by the Javanese, and, by being exposed in the hollows of split bamboos to the rays of the sun, deposits crystals of salt."

Rivers. Java is watered by a great number of rivers, which descend from the central chain of mountains; but, on account of their shallow channels, and the sand banks at their outlets, none of them is navigable by vessels even of a moderate size. All along the coast of the island, high and low water occur only once in 24 hours, and the changes of the moon have no influence on the tides.

Roads. A military road traverses the island nearly from west to east for upwards of 700 miles; and will remain a monument of the perseverance and enterprize of General Daendels. Twelve thousand men are said to have perished in its formation, from the insalubrity of the tracts through which it runs. It is conducted over mountainous regions of vast extent, through immense forests, and numerous marshes and rice fields. There are numerous roads in the environs of Batavia, shaded with trees, ornamented with handsome villas in their vicinity, and crossing in various directions rivers and streams on stone and timber bridges. The new eastern road towards Buitenzorg presents every advantage for expeditious travelling. On this road, extending as far as Kalatigas, 700 miles east of Batavia, there were formerly regular post stages at every five or six miles; but the relays of post horses have been lately withdrawn between Buitenzorg and Samarang, and the same facility of passing through the regencies does not now exist. The ordinary country roads in the interior are passable only for the native carts drawn by buffaloes.

Towns and stations. The principal towns and stations in Java, besides Batavia the capital of the country, are Weltervreeden, Cornelis, Bantam, Samarang, Solo or Soura Carta, Djoejocarta, and Sourabhaya. Weltervreeden, about

---

[*] By Ptolemy it is called the Island of Barley, and its name Yava is said to have that signification; but the grain is unknown to the inhabitants, and will not grow in the island, except in some mountainous tracts, where it has been raised by Europeans as a curiosity.

Towns and stations. **Weltervreeden.** three miles from Batavia, was selected by the Dutch government as a military station, being greatly preferable in point of healthiness and local advantages to any other spot in the vicinity of the capital, and is now the head-quarters of the British troops. To this place General Daendels had intended to remove the seat of government, and all the public offices both civil and military; and, for this purpose, a large commodious building had been nearly completed before the capture of the island by the British. **Cornelis.** Cornelis, a few miles from Weltervreeden, was the field of action in the recent invasion of the island; but few traces of its fortified lines now remain, as the works have been razed, and the fertility of the soil has already spread a wide jungle over the spot where British valour decided the fate of Java. **Bantam.** About sixty-one miles west from Batavia are situated the ruins of the once flourishing city of Bantam, in a low situation, surrounded by jungle and stagnant waters, and remarkable for the insalubrity of its climate. **Samarang.** Samarang, about 343 miles from Batavia, is the chief central station on the island, and has a considerable European population. It is a large town, defended by a stone parapet and rampart, with bastions, and a wet ditch. The town has a neat appearance, and a number of good houses; a large church, a new town-house, and a variety of public buildings, both elegant and commodious, are within and without the city. The climate is greatly preferable to that of Batavia, and has a corresponding effect on the European inhabitants. The environs are ornamented with numerous villas; and beautifully variegated hills and dales enhance the scenery. **Solo.** Solo, or Soura Carta, the capital of the Soesoehoenan, or emperor, is a large populous town, 61 miles from Samarang. The crattan, or residence of the emperor, is very spacious, and contains several palaces in its area. The European town and fort are very neat; and the latter, about 800 yards from the Crattan, contains a British garrison. The Dutch had acquired such ascendancy over the native princes, that they were allowed to erect forts close to their respective capitals, by means of which they forcibly secured the influence which they had artfully obtained. **Djoejocarta.** Djoejocarta, about 87 miles from Samarang, is the residence of the sultan of that name. The population within the Crattan is very considerable. At the entrance on the north side is an extensive square for the exhibition of fights of wild beasts, and various tournaments. The interior of the Crattan is filled with palaces, the most remarkable of which is an ancient edifice in the midst of a large lake. The only entrance is by a covered way under water, to which light is communicated by windows, in turrets which appear above the surface. **Sourabhaya.** Sourabhaya, a large town with a numerous population, European, Chinese, Javanese and Malayan, 540 miles from Batavia, is situated on a fine river, which vessels of some burden navigate up to the town. The mouth of the river is defended by Fort-Calamaas, a circular battery, mounting 40 guns. General Daendels expended large sums in the construction of works for the defence of the harbour, and designed to render the place a principal port for the trade to the eastward. Guns were cast, and a fine arsenal formed; and vessels were built from the timber which the neighbouring forests supplied, and which was floated down the river. The British resident lives at Simpang, in a large building close to the river; and in the same quarter is the general hospital, almost unrivalled for extent and commodiousness. The country in the vicinity is accounted healthier than most other parts of the sea-coast, and the district is exceedingly populous and productive.

History. The early history of Java is entirely lost in the fables of antiquity. Its annals give accounts of political relations having subsisted in more modern times between the island and various states in Sumatra and Borneo; and this is partly confirmed by the circumstance of the written language and the language of the court in these districts being Javanese, while the indigenous dialect is entirely different. **Government.** History and tradition relate that the inhabitants of Java were once united under one sovereign, which is corroborated by the similarity of their language and institutions; but when the Dutch first established themselves in the island, about the year 1619, it was divided into three great states, namely, Bantam, Jacatra, and the empire of the Soesoehoenan, or emperor; which last was the most extensive, and comprehended more than two-thirds of the whole island. It is at present divided into five principal states or governments, namely, Bantam, Jacatra, Cheribon, the empire of the Soesoehoenan, and that of the Sultan. Bantam, which lies towards the south-west, is separated from Jacatra by a narrow slip of land called Grending, and by a chain of mountains called Goenong Tjeberum, terminating to the south in the bay of Wynkoopsbergen. In 1751, it became subject to the Dutch East India Company, who had been invited to interfere in its intestine commotions: (See Bantam.) Jacatra, rather larger but less populous than Bantam, was conquered by the Dutch in 1619, and taken entirely under their government, who built Batavia near its ancient capital Jacatra: (See Batavia.) Cheribon, about half the size of Jacatra, and situated to the east of it, is divided between two princes, who are feudatories of the Company. The empire of the Soesoehoenan, before the war of 1740, comprehended all the rest of the island to the east of Cheribon; but, after that period, thirty of its fifty-six provinces were ceded to the Company, and seven to the Sultan Manko Boeni. Of these seven provinces the most extensive and important is that of Mantaram, which is washed by the southern ocean. All these princes were vassals of the Company, to whom they were bound to deliver all the produce of their respective countries at fixed prices, and to act with them offensively and defensively against every enemy. The whole of these countries were divided by the Dutch into 123 districts, in each of which they established a resident to secure the fulfilment of their commercial privileges, and also a native chief or governor, called Tomogong, to collect the produce payable by the peasants for the use of the sovereign, the Dutch and themselves. The Dutch, especially in later times, held the supremacy in the island by a very precarious tenure; and were obliged to adopt the policy of fomenting disunion among the more powerful native princes, who governed as their tributaries and allies, as well as of bringing large reinforcements of troops from Europe to keep them in due subordination. In the year 1811, a British armament sailed from India against the settlements in Java, and speedily succeeded in reducing the whole island under the dominion of the East India Company.* Its new masters immediately instituted numerous schemes for its improvement; and, in a short time, rendered the greatest benefit to the whole community, by clearing and cultivating the waste and unhealthy grounds around the capital, by abrogating the

---

* See an account of the capture at the conclusion of this article.

extreme severity of the Dutch code, in the punishment of crimes, while the police was rendered more effectual for their prevention; by collecting the revenue in a more equal and less oppressive manner, and by augmenting the colonial and coasting trade of the island. All the courts of justice were modelled on the plan of those of Great Britain, so as to separate the judicial from the police duties, and insure the more prompt and impartial administration of justice. The principal courts were established at Samarang, Sourabhaya, and Batavia, which last was supreme. Regular customhouses were appointed at the same places; and no vessels were allowed to enter for trade at any other port in Java. At Batavia a duty of 6 per cent. and at Samarang and Sourabhaya of 8 per cent. *ad valorem*, was levied on all goods and merchandise imported by sea, and required to be paid within one month. Cloths, which were the manufacture of native eastern ports, paid 15 per cent.; and 12 per cent. was laid upon all European and Chinese goods imported in European and Asiatic vessels. Goods transferred in the roads paid the same duties, as if actually landed for sale; but on goods landed for exportation, and not for sale, the importer paid half duty on the invoice value, and gave security that they should not be sold on the island. All goods and merchandise having paid the import duty were exempted from export duty. For the defence of the island, a Javanese corps of 4000 men was raised, and 1500 men of one of the native princes taken into British pay, and clothed with the British uniform. Instead of the indefinite exactions, and forced services, and inadequate rates of price for the native produce, imposed by the Dutch, a moderate land-tax, equitably arranged, was exacted by government for the security of property and protection of person. This new duty, fixed and explicit, was acceded to by the natives with universal satisfaction, and paid with the utmost alacrity. The exertions of the cultivators being thus encouraged by the certainty of possessing whatever they should raise beyond the proportion paid to the government, the agriculture of the island was remarkably improved and extended. The revenue, instead of being diminished, was raised to six times its former amount. In 1808, under General Daendels, it was only 818,128 rupees; while in 1814, under Governor Raffles, it amounted to 5,368,085, leaving a clear surplus revenue of 2,800,000 rupees per annum. In this flourishing condition the island of Java has been restored by treaty to its former masters; a measure to which the native authorities are said to have manifested the greatest reluctance.

Climate. In Java, as in most tropical climates, the year is divided into two seasons, namely, the east or dry monsoon, and the west monsoon or rainy season. The east, or good monsoon, commences in the month of April or May, and terminates about the end of September or beginning of October. During its continuance, the sky is generally clear, (except that sometimes in the evening, and towards the end of the season, a thunder cloud comes down over the mountains,) and the trade winds blow from four or five leagues off shore, through the whole of the Indian seas to the south of the line, from the south-east, and east-south-east. The west or bad monsoon, generally begins about the end of November; and, while it continues, the westerly winds often blow with great violence, accompanied by heavy torrents of rain, and storms of thunder. About the beginning of March, they become more variable, till they give place in April to the easterly winds. March and October, with part of the preceding and following months, are called the shifting seasons, or the breaking up of the monsoons, and are considered as the most unhealthy periods of the year. Along the whole coast, the alternate land and sea breezes blow regularly throughout the whole of the year, and greatly moderate the intensity of heat. During the east monsoon, the sea breeze is generally confined between north-east and north; but, in the west monsoon, it goes as far as north-west. It begins to blow about 11 or 12 o'clock in the forenoon, and increases gradually until evening, when it imperceptibly dies away to a perfect calm about eight or nine. The land wind begins at midnight, or a little before, and continues till an hour or two after sun-rise, when it falls calm, till the accustomed hour of the sea breeze. From the month of July to November, the thermometer on the coast generally ranges between 80° and 90° during the hottest time of the day; and, during the coolest part of the morning, is seldom lower than 76°. In ascending towards the higher grounds, the warmth of the atmosphere gradually diminishes from 85°, the ordinary heat in the plain, to 50°, the temperature experienced on the summit of the mountains, which are even occasionally covered with snow. In the highest parts that are cultivated, the heat during the day is from 60° to 65°, and at night as low as 54°. The climate on the coast, and especially at Bantam, is more pernicious to the health of Europeans, than that of any other country where settlements have been formed. Of persons newly arrived, the usual calculation is, that three in five will die during the first year, and of the survivors from nine to twelve in the hundred annually; exclusive of the troops and seamen, among whom, in consequence of their irregularities, the mortality is truly deplorable. The weight of the air is nearly the same throughout the year; but does not possess so much elasticity as in northern regions. The barometer seldom varies more than two or three tenths of an inch; and experiments in electricity do not succeed so well as in Europe.

Soil. The soil of the island is generally a pure vegetable mould, resting on clay, or argillaceous iron-stone, or coarse limestone of a loose and porous texture; and is equal in fertility to that of any country in the world. The northern coast rests entirely on coral fabrics; and, near the foot of the mountains are several mineral springs impregnated with iron; but nothing more is known of the mineralogy of the country.

Productions. The soil in its natural state is covered with the most luxuriant vegetation, and yields a great variety of valuable and curious productions. Many places are covered with thick forests, rendered impenetrable by the quantity of underwood and creeping plants, forming a kind of net-work, through which a passage cannot be effected without the aid of a cutting instrument. Forest-trees. The large forests, which belonged to the Dutch India company as sovereigns of the country, especially those on the north-east coast, furnish an abundance of timber for ship-building and other purposes. In these native woods, the numerous tribe of palms or cocoa nut trees are distinguished by their luxuriant growth, and sometimes reach the astonishing height of 150 feet. This tree is to the natives of Java what the bamboo is to those of China. Its stem furnishes the standards, rafters, and laths of their houses; and its leaves are used as thatch. The pulpy substance of the nut affords a sweet and nutritive food; the liquid which it contains, an agreeable and refreshing beverage; and the kernel yields by pressure a useful oil for various purposes.

The shell of the nut is converted into cups, which are often carved with wonderful neatness and skill; and the fibres of the husk are manufactured into mats, coarse cloth, and cordage. A milky fluid also which exudes from the young nut during its growth, is collected by the natives with great care into vessels suspended at the extremity of the branches, which in its first stage of fermentation is called palm-wine, and in its second becomes a pleasant vinegar. It is a material ingredient in the distillation of arrack; and, if slowly evaporated over a fire or in the open air, leaves as a residue a kind of coarse brown sugar. The celebrated *upas*, or poison tree, described as situated in the centre of the island, and destroying by its noxious effluviæ all animal and vegetable life in its vicinity, to the extent of ten or twelve miles around, is now ascertained to have no real existence. There are in Java several plants and trees, from which a poison called *ipo* or *upas* is extracted; but these are generally found in the most fertile places, surrounded by the most luxuriant vegetation.[*] Fruit-trees. Fruit trees of various kinds are remarkably abundant; and many of them extremely beautiful. The most remarkable, is the Mangoostan, accounted the most delicious fruit in the world, equally pleasing to the eye and gratifying to the taste, of a round form and purple colour; and growing on a very beautiful tree, which bears like the orange both fruit and flowers at the same time on the extremities of the branches. The mango, another exquisite fruit, grows on a large spreading tree like the walnut. The rambootan, a hairy fruit, a cool and agreeable fruit of a delicate sub-acid flavour, grows on a showy and elegant tree. The doorian, a large fruit, resembling the bread-fruit in appearance, of a most disgusting smell, and of a flavour like a custard, seasoned with garlic, but said to become by frequent use extremely fascinating, grows on a lofty tree with small pointed leaves. The boa lansa, in great estimation among the lower classes, grows upon a tree of a moderate size, in clusters like grapes, of which each individual fruit resembles the famous li-tchi of China, and has a pulpy substance with a delicate sub-acid taste. Pine apples are produced in such abundance, that they are sent to market in cart loads, and sold at the rate of a halfpenny a piece, but are not much esteemed in the country, except for preserving. Out of many other fruits, may be mentioned the atrocarpus or jack fruit, which grows wild in great abundance; the averrhoa much used for tarts and pickle; the eugenia or rose apple, sweetsop, custard apple, dates, pomegranates, tamarinds, figs, guavas, annanas, bananas, oranges, lemons, citrons, shaddocks, grapes, melons, and pumpkins. Most of the fruits of Europe have been transplanted to the island; but except strawberries and a few others, which are said to thrive in the interior parts of the country, most of them are found to dwindle and degenerate in that equinoctial climate. Remarkable trees and shrubs. Among the trees and shrubs which are remarkable for singularity or beauty, may be noticed the casuarina equisetifolia, whose pendant branches resemble the hair of the cassowary; the mitchelia tchampaca, bearing flowers of an exquisite fragrance, which yield by distillation a spirit more powerful, but not less delicate, than the perfume extracted from roses; the terminalia catappa, a large and beautiful tree, bearing a nut, usually known by the name of the Indian almond: the bombax, which bears a long pod full of a silky substance, used for stuffing cushions, &c. the coral trees, lyriodendrum, tulipifedrum, magnolia, milia, bignonia, all showy and elegant trees. The gardenia florida, Arabian jasmine, clove, cinnamon, tuberose, nutmeg, plumeria, seree or lemon-grass, are cultivated in the gardens on account of their beauty and fragrance. Among the rarer plants are the elastic gum-tree, the convolvulus Jalappa, the styrax liquida, the bread-fruit, and the mountain cabbage-tree of the West Indies. But the most extraordinary vegetable production of Java, and the other eastern islands, is the nepenthes distillatoria, or pitcher plant, which is found in the most arid situations, but is provided with a curious contrivance for securing a sufficient supply of moisture. To the footstalk of each leaf is attached a small tube, shaped like a pitcher, covered with a lid, which is moveable on a kind of hinge or strong fibre passing over the handle, and connected with the leaf. By the contraction of this fibre the lid is opened, when the weather is showery or the dews fall; and, when the moisture has filled the pitcher, closes again so firmly as to prevent evaporation, securing the water for the sustenance of the plant.

Agricultural productions.

The agricultural productions of the country are highly valuable in a commercial point of view, and are raised with little trouble by the native cultivator. The soil is slightly tilled by a clumsy plough drawn by one or two buffaloes; and the only manuring, which it receives, consists in burning upon the fields all the weeds and rubbish, which have sprung up on their surface. When a piece of ground ceases to yield an adequate crop, it is merely suffered to lie fallow for a few years, to bring it again into a fertile state. Garden grounds are moistened with water, in which oil-cakes and various excrementitious substances have been dissolved, which renders the soil extremely productive. The principal production of Java is *rice*, which in whiteness, flavour, and other qualities, excels that of all the eastern archipelago, and ranks next to that of Japan. The island produces this grain in such abundance, that it has been called the granary of the East. Besides furnishing a sufficiency for its own consumption, it supplies many of the adjacent countries, and all the more easterly Dutch settlements. In the year 1767, the quantity of 14,000 tons was sent to Batavia, Ceylon, and Banda. In reaping the rice, a small knife is used instead of a sickle, with which every stalk, singly, is cut about a foot below the ear, and they are then bound in sheaves, the tenth of which is the reward of the reaper. The rice is separated from the husk, by stamping it in hollow wooden blocks; and the more it is stamped, the whiter it becomes when boiled. The next staple commodity of Java is *pepper*, of which there are various kinds, and which is chiefly produced in the western parts of the island. The whole quantity produced in the country amounted, in 1777, to six millions of pounds weight, and the regulated price at which the king of Bantam was then bound to deliver it to the Dutch Company, was about two pence halfpenny per pound. The pepper of Java is esteemed next in point of quality to that which comes from the coast of Malabar. *Sugar* is raised in Java in considerable quantities, but chiefly in the province of Jacatra. In 1768, the whole produce exceeded fifteen millions of pounds, and was capable of being greatly augmented. The cane grows luxuriantly, and is a favourite object of culture with the Chinese inhabitants, who are the great planters and manufacturers of sugar on the island. It is planted from September to April, and

---

[*] See Memoir by M. Leschenault in the *Annales du Museum d'Histoire Naturelle*, cap. xi. and xii. p. 457.

Agricultural productions.

stands twelve or fifteen months on the field, according as the land is rich or poor; and if the soil be good, it can be cut four times. The sugar, after being manufactured, is divided into three kinds or qualities, of which the first is sent to Europe, the second to India, and the third, which is the brownest, to Japan. *Coffee*, though not indigenous, is raised in large crops, especially in the provinces of Cheribon and Jacatra. It was introduced about the year 1720 by Governor-General Zwaardekroon, who procured the plants from Mocha. It is cultivated in the same manner as in the West Indies; and, in 1768, about five millions of pounds were produced on the island, which did not cost the Company above two pence halfpenny per pound. The *cotton shrub* is cultivated in almost every part of the island, except Bantam, where very little of it grows. The yarn spun by the natives is sold to the Company according to its quality, from 9d. to 1s. 6d. sterling per pound. *Salt* is brought in considerable quantities to Batavia from Rembang, and is exported chiefly to Sumatra, where it is sold at an immense profit. *Indigo*, though not originally produced in Java, has been cultivated with great success since the Dutch had possession of the country, and is exported principally to Europe. *Turmeric* and long pepper, sago and cocoa, are among the productions and exports of the island. The *catjang*, a species of dolichos, is extensively cultivated by the Chinese inhabitants for the sake of the oil, which is expressed from the seed, and of which a considerable portion is sent to China. The cajaputta oil, expressed from the melaleuca leucadendrum, and so celebrated as a specific in rheumatic affections; the nardus or spikenard, sandal wood, and calambac or aloes wood, are also products of Java, and form a part of its trade with China. The cassia fistula, once considered as one of the most approved laxatives, was formerly sent in great quantities to Europe. The roots of the water caladi (the arum esculentum) are boiled as an article of food, and its broad leaves are considered as an efficacious topical application for dispelling the pains of the gout.

Animals.

Horses.

Buffaloes.

Buffaloes.

Lacerto Gecko.

Boa.

Birds.

Insects.

Fish.

Of the numerous animals found in Java, a few only of the more remarkable can be noticed. The native horses are well formed, but of a diminutive size, and extremely vicious. They are trained in a very remarkable manner for hunting antelopes. When the game is started, the sportsman pursues at full speed, lying close to the horse's neck and regardless of the reins, as the horse follows the prey like a greyhound; and, on overtaking the antelope, endeavours to secure it by throwing a noose over its horns. Should the rider lose his seat, the horse nevertheless continues the pursuit; and instances have occurred of his pawing the antelope to the ground, or by mouthing and kneeling, holding it fast till the arrival of the hunting party. Buffaloes are generally employed in the draught, both for ploughs and carts. They are very large animals with small eyes, great ears, and commonly immense horns bending inwards. They are almost amphibious, remaining always in ponds, unless when obliged to go in quest of food; and when domesticated, requiring to be led three times a day to cool themselves in the water, without which they could not be brought to work. Antelopes are found in the forests, and are frequently kept in parks by the princes. The rhinoceros of Java is of a huge size, and found chiefly in the mountainous districts. In the eastern part of the island are large uncultivated tracts, covered with thick woods, abounding with tigers, wild buffaloes, wild hogs, leopards, and very large apes. For one species of the monkey tribe, called the Wow-wow, the Javanese profess a kind of fellow-feeling, in consequence of a tradition among them, that their ancestors originally sprung from that species of ape. There is a species of wild hedgehog, which sometimes contain in their gall bladder a stone, called by the Portuguese the pedra da porco, and considered by the Dutch as possessing the most wonderful medicinal properties. When put into a glass of wine for an hour, its virtues are supposed to be communicated to the liquor, which is then used as an infallible specific for all kinds of poison, for obstructions, fevers, and various other diseases. One species of lizard, called Lacerto Gecko, a native of Java, is peculiarly deserving of notice, for its wonderful faculty of walking, apparently in opposition to the laws of gravity, running up and down the smoothest polished Chunam walls, in pursuit of flies, and able to take so fast a hold of a smooth perpendicular surface as to carry up a weight equal to that of its own body. (See HERPETOLOGY, vol. xi. p. 29. where the mechanism is described by which this is effected.) Large crocodiles abound in the rivers and creeks, which the inhabitants, under the influence of terror, have made the objects of adoration. The great boa snake is even of greater magnitude, and a more formidable nature than these alligators. Some of them have been killed in the forests which were 30 feet in length, and capable of swallowing whole the largest hogs. The forests and mountains produce an immense variety of the feathered race, from the large cassowary to the minute humming bird. Of those which are most distinguished for the beauty of their plumage, may be mentioned the argus pheasants, fire-backed pheasants, crowned pigeons, birds of paradise, golden thrush, king's fisher, Java sparrows, or rice birds, and many of the loories and paraquets. The insect tribes are extremely numerous: snakes, scorpions, spiders, ants, musquitoes, fire-flies, and many other dangerous and disgusting vermin, swarm in the roads, houses, and even bed-chambers. A venomous spider is very common in the thickets, the body of which is nearly two inches in diameter, the fore legs or claws four inches in length, and the webs spun by it so strong as frequently to entangle and catch the smaller birds. Every object, indeed, in this country, seems impregnated with life. The bay of Batavia, swarming with myriads of living creatures, exhibits a phosphorescent light during the night-time; and a glass of water taken out of the canal, becomes in a few hours a collection of animated matter, the minute portions of which, multiplying by division and subdivision, move about with astonishing rapidity. The coasts of the island abound with excellent fish, one species of which, called the Jacob Evertzen, often weighs 400 lbs.; sharks infest the bays, and swim boldly around the ships; and many animals still unknown in natural history, are said to frequent the shores of Java.

Commerce.

The commerce of Java is very considerable, as, besides its own productions, it used to be the general depot of all the spices of the Moluccas. It is, properly speaking, however, merely an exchange trade, as all exportation of cash or bullion is expressly prohibited; and even the dollars which a merchantman may bring to the ports, are not allowed to be taken away again, but must all be expended on goods. All traders were generally farther restricted by the Dutch Company as to the nature of the cargo which they wish to export, and were required to take one-third or fourth of it in spices.

Commerce. The trade in certain articles, such as opium, camphor, benzoin, calin (a sort of Indian metal,) pewter, iron, saltpetre, gunpowder, &c. was, under the Dutch, reserved exclusively for the company, and the opportunities of gain by private trade have been gradually decreasing since the middle of last century. The principal exports from Java have been already noticed under the head of its productions; but the greater portion of the articles imported from other eastern countries, may be considered as intended more for future exportation, than for the use of the island. From Bengal are brought patnas, blue cloths, and other stuffs, drugs and opium; from different ports in Sumatra, camphor of the best quality, benzoin, calin, elephants teeth, and birds-nests;[*] from Borneo, gold-dust, diamonds, and birds-nests; from Europe, kersymeres, cloths, hats, gold-wire, silver, galloon, stationery, wine, beer, dollars; from Muscat, dollars and gum-arabic; from the Isle of France, olive-oil, wine, vinegar, hams, cheese, soap, trinkets, ebony, mercery; from the Cape of Good Hope, garden-seeds, butter, Madeira, and Constantia wines; from China, immense quantities of porcelain, and silks of every kind; from Japan, camphor, fans, articles of furniture, sabres of an excellent temper, and ingots of fine copper for common coinage to pay the troops.

Money. Money, especially of gold, is very scarce at Java; and the current coins are a mixture of Dutch and Indian pieces, of which the following Table gives the value in sterling money, at the par exchange of eleven francs per pound.

	Francs.		£	s.	d.
The old Japan gold coupang	24	0	2	3	$7\frac{1}{4}$
The new ditto . . .	14	8	1	6	$2\frac{1}{4}$
The milled Dutch ducat . .	6	12	0	12	0
The silver-milled ducatoon .	4	0	0	7	$3\frac{1}{4}$
The unmilled ditto . .	3	18	0	7	1
The Spanish dollar or piastre from	3	3	0	5	$8\frac{3}{4}$
to	3	6	0	6	0
The rix dollar	2	8	0	4	$4\frac{1}{4}$
The Batavia rupee . . .	1	10	0	2	$8\frac{3}{4}$
Other rupees about . . .	1	7	0	2	$5\frac{1}{2}$

There are likewise half-rupees, quarter rupees, and fanams, equal to one-twelfth of a rupee. There are copper coins issued by the Company, particularly the stiver, of which eighty-eight are equal to a rupee; two-penny pieces, equal to two stivers; and doits or farthings. The rix-dollar, equal to 48 stivers, is the money chiefly used in private trade; and the milled silver ducatoon, equal to 66 stivers, was the current coin of the Company through their Indian possessions. A paper currency, issued by General Daendels during the late war, and termed Porbolingo paper, was common in the island at the time of its capture by the British, but was by them tended to be gradually called in and abolished.

Weights and measures. Most merchants goods are calculated by the picol of one hundred and twenty-five pounds Amsterdam weight, which is subdivided into a hundred cattis, each weighing one pound and a quarter. Sugar is taken in canassers of three picols, or 375 pounds each; coffee, in bags of 252 pounds; and cinnamon, in bales of eighty. Rice and other grain is measured by coyangs, which must weigh, when originally purchased by the Company, 3500 pounds; but which, by deductions for dust, drying, perquisites to the warehouse keepers, and other hands through which they pass, are finally reduced, when the article reaches the consumer, to 3000 pounds. There is also a small rice measure of $13\frac{1}{2}$ lbs. called ganting.

Inhabitants. The general population of Java has been variously estimated; by Valentyn at 3,300,000; by the gentlemen of Lord Macartney's embassy in 1792, at 2,300,000; by a census, said to have been taken by General Daendels, in 1808, the returns, exclusive of the south coast, exceeded 3,000,000; and by the latest surveys of the British, there are supposed to be 5,000,000 of persons on the island. The inhabitants, especially around Batavia, are composed of various tribes; but principally of native Javanese, Malays, Chinese, and slaves.

Javanese. The Javanese live in a state of absolute slavery to the native princes, except that they are not transferred by sale from one master to another. The form of government among them is perfectly despotic, and the power of the prince in every sense uncontrouled. His will is literally the law, and is restricted by no regular institutions, either civil or religious. There are no hereditary distinctions or ranks among the people; but, by the mere authority of the monarch, the humblest may be raised to the chief dignities, and the highest degraded to the state of the meanest subject. They have no security in their property, or power to dispose of it, farther than the sovereign may permit. The land, particularly, is his exclusive property; and, in place of salaries to the officers of government, portions of ground are allotted and revoked at pleasure. Neither grant nor occupation can convey to a subject the remotest claim to permanent possession; but large tracts of territory are frequently given one day, and resumed the next; and scarcely an instance occurs of lands being held by the heirs of those who occupied them 30 years ago. The poorest peasant is not even at liberty to dispose of the fruits of his own industry at his own pleasure; but is bound to carry the whole, or a part, either to the company or the prince, at a regulated, and frequently most inadequate price. Though the unbounded prerogatives of the sovereign, and this fluctuating state of property, cannot admit a hereditary nobility, there are nevertheless a privileged class, who receive titles and extensive powers at the pleasure of their despot; and who are proportionally revered by the superstitious people as representatives of royalty. The distinction between the people and these privileged orders is extremely marked and humiliating, and extends even to the language, of which the men of rank speak one dialect, and the plebeians another. The language is even adapted to the different gradations of rank; and the sovereign particularly often makes use of one dialect, which no subject dare use, and is spoken to in another, which can be addressed only to himself. When a Javanese, in short, approaches the presence of his prince, his great object is to express the immeasurable inequality between his condition and that of the sovereign. He assumes, therefore, the most abject position of body, rather crawling than walking; shews his respect not by decency of attire, but anxiously displays his relative meanness by studied raggedness or partial nakedness; and instead of recommending himself by the elegance of his language, selects the dialect of the most ignorant slave, or mimics the barbarous idiom of a despised stranger. It is the custom to express respect, not by standing, but by sitting in the presence of a superior; and even the slaves who attend as menials, squat at the feet of their master or mistress, instead of placing themselves behind their back. The

[*] See CHINA, Vol. VI. p. 300—Note †.

natives of Java are generally about the middle size of Europeans, straight and well made, steady and upright in their gait, affecting a superiority over the other inhabitants. Their eyes are black and prominent, the forehead broad, the nose somewhat flattened and curving downwards at the point, the upper lip rather projecting and arched, the joints of their hands and feet remarkably small, and especially in the female sex remarkably pliant, so as easily to bend backwards. The colour of their skin is a deep brown, their hair black, and kept constantly smooth and shining with cocoa-nut oil. Black is also the favourite colour of the teeth, which are all stained of the deepest hue, except the two in the front, which are covered with gold leaf. Children of both sexes go entirely naked till their eighth or ninth year; or, at most, the young females wear a belt round their loins with a broad metal plate in front. The dress of the men among the common people consists of a piece of cotton wrapt round the waist, drawn between the legs, and fastened behind, with a handkerchief or small cap upon the head. Persons of a higher class wear a wide Moorish coat of flowered cotton or other stuff, and generally turbans instead of caps. They eradicate the hair from every part of the body except the head; and rub the face, and other parts not covered by clothing, with a composition of cocoa nut oil and sandal wood dust, as a preventative against too copious a perspiration, and the bites of insects. The dress of the women nearly resembles that of the men. It consists of a piece of cotton or chints called saron, wrapt round the body as high as to cover the bosom, and hanging down to the knees or ankles. Over this they sometimes wear a short jacket, but generally the shoulders and part of the back remain uncovered. They have no covering to the head, but wear their hair bound in a fillet, and fastened behind with large pins of woods, tortoise-shell, silver or gold, according to the rank of the lady: this head-dress is frequently adorned with a variety of flowers. Both sexes are remarkably fond of bathing, especially in the morning; yet are in other respects very filthy in their persons.

The dwellings of the lower orders are rather huts than houses, constructed of bamboo, plastered with mud, and thatched with leaves of the cocoa-nut tree. There is seldom more than one apartment for the family and poultry; and the furniture generally consists only of a bedstead of bamboo, a few pots for boiling their victuals, a hollow block for pounding the rice, and a few cocoa-nut shells as drinking vessels. They are sufficiently temperate in point of diet, in consequence of their extreme poverty, yet altogether indiscriminate, and even voracious, as to the nature of their food or times of meals. Their common article of subsistence is rice, boiled with a little fish or capsicum, or salt, and the fruit of the cocoa-nut; but in the mountainous regions, where rice is not raised, they make use of a certain root called tallas, with the salt which they procure from wood ashes. Notwithstanding, in short, the fertility of the country, the oppressed inhabitants are little better than starving savages. They are continually chewing betel or pinary, or rather a composition of the areca nut, lime of shells, and seeds of long pepper, made into a paste, and rolled up in a green leaf of betel-pepper, which communicates to the tongue and lips a deep red colour, afterwards turning to a dark mahogany brown. The areca nut, especially when fresh from the tree, has a strong narcotic power, and a small portion will intoxicate those who are not accustomed to it. They are fond of opium, and indulge freely in intoxicating liquors at their religious ceremonies; but the greater part of the people stupify themselves with the less expensive articles of tobacco and bangue.

Medicine.

Though subject to few diseases, they are not long lived; seldom exceeding the age of 50, and very few attaining threescore years. Their physicians, who are frequently females, though ignorant of anatomy, are said to produce surprising cures by their knowledge of medicinal herbs, and by the use of friction with oil.

Marriages.

The Javanese are polygamists, and marry as many wives as they can maintain; besides keeping a retinue of female slaves as concubines, but the lower classes have seldom more than one wife. They are said to be extremely indifferent with regard to the chastity of their females, and to be in this respect the most depraved people in the world. Their women are more comely than the men, but become extremely ugly as they grow old. They are much attached to Europeans, and fatally jealous of losing their affections.

Amusements.

A Javanese person of rank spends most of his private hours in the society of his women, smoking his hooka in placid apathy, while they are dancing before him, or listening to their narrations of traditionary stories, or the adventures recorded in the sacred books. The principal amusement of a more active nature, is a kind of tennis-play, at which they are remarkably dexterous, striking the ball (which is about the size of a man's head) with their feet, knees, or elbows, and keeping it in continual motion like a shuttle-cock. They are also extremely fond of cock-fighting, for which they keep a particular breed of a prodigious size, nearly as large as the Norfolk bustard. Instead of spurs, they fix to the bottom of the foot a piece of sharpened iron shaped like a scythe, and about the size of the blade of a large penknife; with a single stroke of which, the bird will sometimes completely lay open the body of his antagonist.

Weapons.

The principal weapon of the Javanese, which they always carry with them, is a kind of dagger called a creese, resembling a small hunting knife, with a blade of hardened steel, of a serpentine shape, and capable, from its form, of inflicting a large and wide wound: Its point also is frequently stained with a mortal poison.

Salutations.

Their mode of salutation consists in touching the forehead with the right hand, accompanied by a slight inclination of the body.

Character.

They are described as proud and cowardly, extremely arrogant in their treatment of persons who are their inferiors, in which light they regard all foreigners; but not less cringing towards their superiors, or those from whom they have any favours to expect. They are remarkably indolent in their habits, and are with great difficulty excited to labour; a disposition, which, considering the industry of the Chinese who reside among them, may be ascribed not so much to the influence of their climate, as to the oppressive nature of their government, which renders them so uncertain of being suffered to possess the property which they may acquire, and thus takes away every motive to active exertion.

Chinese.

The Chinese inhabitants of the island are very numerous, especially around Batavia, where the poll tax paid only by the men yields 40,000 rix-dollars, where they are calculated to amount to 100,000 souls. Their appearance, dress, and character is every where the same, as in the empire of China; but in Java their extraordinary industry forms a striking contrast with the laziness of the other inhabitants. Though severely taxed by the Dutch, they generally found means to accumulate wealth. In all the towns they are the great holders of capital, and carry on a considerable trade wth their native country, and the several islands in the Eastern Archipelago, as well as around the coast of Java. They are the principal shop-keepers, the most skilful gardeners, the most ingenious artificers, on the island. They are free masters of whatever they can earn by trade or agriculture, beyond the assessments levied by the Company's government; and in the rational hope of obtaining the reward of their exertions, they readily undertake the most toilsome occupations, which the oppressed and plundered Javanese would regard and would probably experience to be lost labour. But, with all these industrious habits, they are extremely addicted to gaming; and the houses licensed for the purpose in their quarter of Batavia, are so numerous as to yield an annual tax of £ 8000. Though sufficiently pusillanimous and effeminate, they are extremely turbulent, and apt to break out into open insurrections, for which they were often punished by the Dutch in the most sanguinary and summary manner, (See BATAVIA); but, of late years, it has been the more humane policy of the Company's government to divert their attention by perpetual amusements, and to keep them in subordination by officers of their own nation.

Malays. The Malays are also a numerous class of the inhabitants of Java, but are a most worthless and ferocious race of people. They are sufficiently active, bold, and enterprising in the pursuit of plunder, and passionately addicted to every kind of gaming. They will frequently stake upon the issue of a cock-fight their last morsel of bread, their whole bodily clothing, and even their wives and children. They are treacherous in their dealings, remorseless in their enmities, and capricious in their friendships. Their rage is of the most ungovernable description, resembling a kind of mental frenzy; and their revenge is inflexible in its aim, however fatal its consequences to themselves. A blow, especially, is an indignity which they never forgive, and which makes them lose all consideration for their own existence. Under the influence of revenge or disappointment, a Malay sometimes adopts the desperate resolution of running a muck (as it is vulgarly called, from the word *amock* to kill); and, arming himself with a dagger, he sallies forth after swallowing a large dose of opium, attempting to kill every person who comes in his way. He is of consequence soon knocked on the head like a mad dog, or sometimes secured alive by means of a long pole armed with iron hooks; and, in this case, was usually put to death by torture, to deter others from imitating the example. But, since the abolition of the gambling houses by order of Lord Minto, not a single instance of these frantic bursts of despair has occurred at Batavia.

Slaves. The last class of inhabitants are the slaves, who are imported chiefly from Malabar, Celebes, Timor, Madagascar and Mosambique. They are distinguished in the towns by having their legs and feet uncovered; and are employed either in domestic services, or trained to useful trades, by which they generally earn for the use of their masters a higher interest for the money expended in their purchase and subsistence, than could be procured by employing it in any other way. The most numerous and useful are Malays, from the different islands of the Eastern Archipelago, who are extremely prompt at imitation, and expert in all handicraft trades. Those from Malabar are mild and passive, willing to be instructed, but slow of apprehension, ill adapted for hard labour, and generally used as personal attendants on their proprietors. Those from Madagascar and Mosambique are also a harmless and pliant race, tall, and athletic, but remarkable for their simplicity, and devoid of all ingenuity. The greater part of the female slaves are brought from Pulo Nias, a small island on the western side of Sumatra, and are greatly esteemed for their smooth skins, elegant shape, and lively dispositions, sometimes selling at the rate of a thousand dollars. The slaves of both sexes are well fed and lightly worked; but frequently treated with great severity. In consequence of the excess in the proportion of females, and the little care taken of their offspring, who are seldom the fruit of a connubial tie, there is required a large annual importation to keep up their number; and it is estimated, that more than a thousand are imported every year for the citizens of Batavia alone. There is little occasion, indeed, for this class of beings in a place where thousands of free Chinese, the best and most handy servants in the world, are ready to serve in every department, on the most moderate terms. Their treatment at least will now be greatly ameliorated, by the abolition of all farther trade in slaves in the British settlements, of which the good effects have already extended to the island of Java.

Language. The Jawa or Javanese language, though now supplanted by that of the Malays, on the coast, is admitted to be the most ancient, and seems to have at one time been current throughout the whole extent of the island. In the interior, not one native among ten thousand can speak the Malay language; and the two people are not in the least intelligible to each other in their speech. The Jawa is sufficiently copious, and overflows with words of pure Sanscrit. The Hindoo names for the days of the week, though now obsolete, are universally known to the learned Javanese. The alphabet of Java is nevertheless peculiar; and has no resemblance, in the order of the characters, to the Deva Nagari. The simple letters are twenty in number, besides compound characters. Each letter has an inherent vowel, as in the Bengalee, which is always pronounced like *a* in the English word ample, and is always sounded in reading, unless when a mark indicates its suppression. The other vowels are always joined to the consonants, and have generally one determinate sound. The compound characters are commonly placed beneath the simple letters; and then the inherent vowel of the upper letter is suppressed, while that of the compound one is sounded. The plural is formed, as in the Malay, by merely repeating the word; and there is no variation on account of number or person in the verbs. The orthography is extremely simple, and the construction not unlike that of the Malay.

Religion. There is satisfactory evidence, that the Javanese once professed the Hindoo religion in some form; but as there is no appearance of the grand Brahminical distinction of casts having ever prevailed among them, it is conjectured that the most prevailing system was that of Buddha. The traditions, however, of their ancient belief, the superstitious observances still extant, and the temples and idols peculiar to the Hindoo worship, with inscriptions in the sacred language of that faith, found in various parts of the island, furnish sufficient evidence, that the tenets of Brahma had also obtained a footing. Many of the penances inculcated in the Hindoo ritual are occasionally practised by the Javanese; and all who are descended of the royal blood, scrupulously abstain from using the flesh of the cow. Many idols of Brahma, Vishnu, Mahadeva, and Bhavani, both of stone and metal, have been found in the island; and that of Ganesa with his elephant head, was frequently recognised by the British officers, during their late campaigns in Java. More than 100 stones were discovered in the interior, covered with inscriptions, which Mr Marsden ascertained to be written in the Square Pali, a sacred character of the Birmans. The most extensive remains of these Hindoo structures are found at Borong Budor (the place of many idols) in the district of Cadoc, at Brambanam, and in the districts of Mataram, and Ballenbouang. In the adjoining island of Bally, the religion of Buddha still predominates; and a few idolaters are found in the eastern mountains of Java; but the prevailing religion at present is that of Mahommed, adulterated by many superstitious relics of the ancient systems. The Mahommedan faith was introduced in 1406, by Sheikh ibn Molana, or Ben Israel, an Arabian, who soon became a powerful sovereign, as well as a venerated apostle in the island. The kings of Bantam and Cheribon claim him as their ancestor; and pilgrimages are performed to his Mosque and Mausoleum, which stand near the town of Cheribon, and are ranked among the most curious antiquities of the Eastern Isles. The Javanese Mahommedans do not bury their dead in coffins, but merely wrap the bodies in a piece of white cloth before being deposited in the grave; and place two stones, one at the head and another at the feet, which they believe will serve as seats to the two angels, who are to examine after death into the conduct of every individual in this world.

History of the capture of Java by the British in 1811.

We shall now conclude this article with an account of the British expedition to Java, abridged from the detailed account published by Major Thorn, an intelligent and enterprising officer, who was himself attached to the staff of the forces employed there; and as the reduction of Java presents a series of brilliant achievements of the British arms, the splendour of which appears not to have been duly appreciated by the public, or to have been lost in the greatness of the efforts of our countrymen in the plains of Spain and Belgium, we shall present our readers with a succinct account of the operations of the army till the final subjugation of the island.

The force destined for the attack of Java amounted to upwards of 5000 Europeans, and an equal number of native troops of the East India Company's service, nearly 12,000 men in all, under the personal command of Lieutenant General Sir Samuel Achmuty, commander in chief at Madras. Of these, about 2500 were inefficient from sickness when they landed at Java. The British armament, composed of 4 line of battle ships, 14 frigates, 7 sloops of war, 8 East India Company's cruisers, 57 transports, and several gun-boats, in all about 100 sail, anchored in the bay of Batavia on Sunday the 4th of August 1811, and the debarkation of the troops took place on the same day, at Chittingching, a village about 10 miles to the eastward of Batavia. As the point of landing was left exposed by the enemy, the debarkation was effected without loss or opposition. It was the commander in chief's intention to advance direct to Cornelis, about nine or ten miles in the interior, where the enemy was posted in force, and to endeavour to penetrate by the route of Batavia, placing that city in the rear, from which he might derive supplies, and keep up the communication with the fleet. In pursuance of this plan, Colonel Gillespie, with an escort of dragoons, reconnoitred the road and country along the coast towards Batavia, to within two miles of the capital. The videttes of the enemy were observed on the other side of the Anjole river, which flowed between them and our troops, and the bridge across which was burnt down. It was a matter of surprize that the country was yielded up as far as this river without dispute, as, from its intricate and difficult nature, an active enemy might have opposed serious obstacles to an advance. The inactivity of the enemy, and the little appearance of force on the Batavia side, together with a serious conflagration in the city, induced the commander in chief to attempt the passage of the Anjole. This was effected without opposition by the advance of the army at 10 o'clock at night, on a bridge of boats provided by the navy, the enemy having contented himself with breaking down the bridges, over the different canals and rivulets, to impede the approach to the city, without risking any actual engagement.

Occupation of Batavia.

The capital being summoned on the 8th of August, the mayor made his appearance on the part of the burghers, to beg protection for them. Although little information of the enemy could be procured from this source, it was ascertained that they were assembled in force at Weltervreeden and Cornelis, the former place being about three miles distant from Batavia. The British began now to experience the consequences of being in a hostile country, the respectable inhabitants having been compelled to retire into the interior, and the water conduits having been destroyed, to cut off as much as possible a supply of water. In this state of affairs it became expedient to act with caution. A small party was pushed into the city to reconnoitre. Several of the enemy's videttes just shewed themselves, and galloped off in the direction of Weltervreeden. The party occupied the town-house, and by their presence rescued much valuable property from plunder and destruction. The town having surrendered at discretion, a royal salute was fired from the shipping, on hoisting the British flag at the crane wharf. Intelligence being received that the enemy meditated a night attack upon the detachment in the town, the men were called out at 11 o'clock at night, and ordered to lie upon their arms. Scarcely had they taken post, when the head of the enemy's column appeared, and opened a fire on the piquet stationed at the bridge leading to Weltervreeden. There was just time to raise the draw-bridge. The firing increasing all around the town, Colonel Gillespie sallied out at the head of a party to charge the enemy's advance in flank. This movement had the desired effect. The firing ceased, and the enemy were seen no more during the night. On the following evening, the town was saved from destruction by the discovery of a Malay, with a fire-brand in his hand, in the act of setting fire to magazines containing a great quantity of gunpowder.

Hitherto we have seen success attending the expedition, in consequence of the remissness of the enemy in obstructing its progress, and in making use of the means of defence within their reach. We perceive a difficult country yielded up without opposition, a river passed without contest, and the capital taken possession of without the loss of a man. General Janssens appears to have been deficient in the use of his light troops, with which he was well provided; and instead of retarding the operations of an invading army, which proves always disastrous to it, he concentrated his chief resources within a short march of the capital, and at once brought on a general engagement, the most desirable object for the British commander.

Success over the enemy at Weltervreeden.

The British force and its guns being transported across the Anjole, the advance, consisting of 1000 Europeans, and 450 Asiatics, under Colonel Gillespie, marched on the morning of the 10th of August from Batavia in pursuit of the enemy. On approaching the cantonment of Weltervreeden, they found the place abandoned by the enemy, who had retired about a mile, to a strong position, on the road to Cornelis. The enemy's right was protected by an artificial water course called the Slokan, and their left by the great Batavia river. Pepper plantations concealed their line, and an abbatis, behind which were planted four horse artillery guns, blocked up the road to Cornelis. Dispositions being made to turn their flank, the object was effected, after surmounting great obstacles; the British troops rushed forward, and charged their artillery with the bayonet. The action lasted, however, two hours, from the impediments and difficulties to be overcome in closing with the enemy. A total defeat at length ensued, with the loss of 500 men, and several officers of distinction, together with four guns. A large quantity of military stores, and 300 pieces of ordnance, were captured in the arsenal at Weltervreeden. Preparations were now made to drive the enemy from their strong position at Cornelis. Here the whole French force, exceeding, 10,000 men, was stationed under the Governor General Janssens, and General Jumel, senior military officer. The position was defended by two rivers on the east and west, both unfordable, and was shut up in a deep trench, strongly palisadoed. Seven redoubts, and many batteries of heavy cannon, occupied the most commanding ground within the lines; the fort of Cornelis was in the centre, and the works were defended by a numerous and well-organised artillery. As the season for field operations was far advanced, the heat of the climate intense, and the British force too small to admit of regular approaches, the commander in chief decided upon carrying the works by assault. Batteries of twenty 18 pounders and 8 mortars were erected to disable the principal redoubts, by the fire of which the enemy were greatly disturbed in their position, and their nearest batteries were silenced. The 26th of August was fixed for the assault. Colonel Gillespie, whom we always find at the post of honour and danger, was appointed to lead the main attack. He was supported by Colonel Gibbs at the head of another column. Colonel Wood was directed to advance against the enemy in front, and if possible open the position for the line stationed at the batteries, while other subordinate attacks were ordered to distract the enemy's attention, and to promote the main object. This object was to surprise a redoubt beyond the lines, and to cross the bridge leading into them with the fugitives, then to assault the redoubts within the lines, Colonel Gillespie attacking those to the left, and Colonel Gibbs to the right. Advancing by a detour through an intricate country, Colonel Gillespie, on approaching the works, learnt that the rear of his column had not arrived. Relying on the prompt and able assistance of Colonel Gibbs, as soon as the fire of the main attack should point out its direction, Colonel Gillespie resolved to advance. Twice he was challenged by the enemy's sentries, and answering "patrole," passed on. An officer's piquet next challenging, the word "forward" was given, and so rapidly was the command obeyed, that the piquet was demolished in an instant. The redoubt was next assaulted and carried with the bayonet, with such celerity, that not a man escaped. Passing forward to secure the passage over the bridge, the attacking column was exposed to a tremendous fire, the spot being enfiladed by all the enemy's batteries. Having succeeded in gaining this point, the key to the position, a second redoubt was warmly disputed by the enemy, and it was not carried till after severe loss on our part. At this moment Colonel Gibbs arriving, he was directed to carry another large redoubt on the right; which having effected in a most gallant style, an explosion of a gunpowder magazine took place, by which many lives were lost. The front of the position was now open, and our troops rushed in from all directions. The enemy maintained themselves in considerable force in front of fort Cornelis, but they were attacked with the bayonet, and completely overthrown. Colonel Gillespie, enfeebled by a slow fever, was overpowered by his extraordinary exertions. On receiving a contusion in the attack of the park, he fainted in the arms of Captains Dickson and Thorn. Having, however, soon recovered, and seeing the cavalry come up, he cut a horse from the enemy's guns, and immediately mounted it. The arrival of his own charger soon enabled him to head the charge in pursuit of the enemy. The route became general; and the pursuit was continued till the whole of the enemy's army was killed, taken, or dispersed. General Janssens saved himself with difficulty during the action; reaching Buitzenzorg, a distance of 30 miles, with a few cavalry, the sole remains of his army. The enemy lost an immense number in killed and wounded, and 5000 men were taken prisoners

Assault of the lines of Cornelis.

Enemy's army destroyed.

Rejection of terms by General Janssens.

After the victory at Cornelis, a verbal offer of terms was sent to General Janssens, which he refused, on the plea of still having resources. The commander-in-chief determined to follow him in person to the eastward; and learning, by intercepted letters, that he had repaired to Samarang on the sea coast, he concerted with the admiral to conduct a force there, and to compel him to abandon the position. A joint invitation was sent to surrender at discretion, in order that the horrors of war might be averted from the colonists; but this was again rejected. The fort of Samarang, which it was deemed expedient first to reduce, was discovered to be evacuated. Janssens, however, having collected a force among the native princes, still occupied a position near the town. The enemy were posted on high and rugged hills, their flanks defended by the extreme difficulty of ascent; 30 pieces of cannon on platforms covered the front, and a valley 1200 yards broad separated the two forces. Notwithstanding the formidable appearance of the position, the commander-in-chief, from imperious circumstances, determined to attack the enemy in front. Colonel Gibbs, at the head of the advance, assisted by the fire of our guns at a great elevation, rushed across the valley. The enemy, paralyzed by the unexpected attack and imposing attitude of the attacking column, made but an ineffectual use of their guns, and were already vanquished. Their guns were abandoned; but the enemy being chiefly cavalry, eluded pursuit. After this last effort, General Janssens, finding himself deserted by his men, sent in a request to the commander-in-chief for a cessation of hostilities, and an offer to submit to terms.

Enemy defeated near Samarang.

General Janssens submits to terms.

Thus, after a short but brilliant campaign, the island of Java was wrested from the dominion of France, and annexed to the number of British colonies. Lord Minto, the governor-general of India, who had accompanied the expedition, having witnessed the triumph of the British arms, and having given publicity to the merit of the army in the records of government, returned to Calcutta, and erected a monument, at his own expence, to the officers who fell in the service of their country. Sir Samuel Achmuty, having left a force deemed sufficient for the protection of the new conquest, also returned with the rest of his troops to Madras.

Dutch colonists massacred at Palimbang.

We shall now call the attention of our readers from the affairs of Java to the neighbouring island of Sumatra, an act of singular atrocity having occurred at Palimbang, in the massacre of the peaceable Dutch colonists by the command of the sultan of Palimbang. To punish this flagitious proceeding, an expedition was dispatched under the command of Colonel Gillespie. Perhaps an account of this expedition might be introduced more properly in the article of SUMATRA itself; but at the same time, regarded as an operation of part of the army of Java, we wish to present our readers, at one view, with a connected account of the military transactions of the period in this quarter. The enterprize about to be related, is of that daring character which places its author in the list of those who have signalised themselves by acts of personal intrepidity.

Account of the massacre.

British expedition to Palimbang.

Batteries at Borang seized.

Confusion at Palimbang.

A small band selected for its relief.

The sultan of Palimbang, taking advantage of the distracted state of Java, adopted the sanguinary resolution of cutting off at one blow the Dutch settlement in his dominions by a general massacre. It was rumoured that this hatred of the Dutch colonists originated in the libidinous habits of the eldest son of the sultan, who, in one of his nocturnal rambles, had been thwarted in his criminal designs upon the wife of a native by the Dutch patrole, brought to her rescue by her screams. The guard, ignorant of the rank of the culprit, pressed him so hard in pursuit, that he was compelled to seek safety in his boat, which he reached with difficulty, by plunging into the river. A thirst of revenge took full possession of the breast of the prince, who vowed to extirpate the colony in language loud enough to be heard by all his attendants. It appears that the sultan was soon prompted to second the barbarous resolution of his son, as two days only after the occurrence, and soon after the news of the success of the British in Java had reached Palimbang, a message from the former arrived to the Dutch resident, desiring him to come to the palace at Palimbang,—an invitation which, contrary to the advice of his friends, the resident imprudently accepted. Armed Malays, under various pretences, intruded themselves one by one into the fort, who overpowering the guards, bound the Europeans and natives of the garrison, and tearing them from their weeping families, hurried them on board prows, prepared for their conveyance down the river, at the mouth of which they were all murdered. They were put to death under the most horrible cruelties, and the prows which contained them were afterwards set on fire and consumed. The unfortunate victims, it is said, amounted to 24 Europeans and 63 native soldiers. But the instigator of this horrible proceeding was doomed to experience speedy vengeance. The armament destined for Palimbang, sailed on the 20th of March 1812, from Batavia, but unhappily, from detention by contrary winds and currents in the straits, ample time was afforded the guilty sultan for flight or resistance. The former measure he had resolved to adopt, having removed his women and treasure into the interior of his country, while both he and his ministers endeavoured to amuse the British commander with declarations of respect, and messages requesting to be informed of the object of the armament. Appropriate answers were returned, with the assurance that the views of the British government would only be confided by the commander of the forces to the royal ear. But the insidious policy of the sultan began fully to develope itself. A message arrived, importing that the sultan would be happy to see his friend the British commander at Palimbang, with a few attendants only, as the presence of so large a force might occasion serious alarm to his subjects. Formidable batteries in appearance, though badly constructed, were placed at Borang, 40 miles from the sea, to guard the approach to the capital. Unmolested passage up the river being demanded of the messenger by Colonel Gillespie, this was granted, and also the occupation of the batteries, which was promised as a pledge of sincerity, a person styled their commandant being left to conduct the British to the spot. The next day, the British advance, with its guns, making its appearance within half gun-shot, the batteries which the sultan had ordered his troops to defend were abandoned by the enemy. Their cannon, amounting to 102 pieces, ready loaded and primed, were taken possession of. A scene of desultory and savage hostility soon spread around. Fires in all directions were kindled, and burning rafts were prepared for the destruction of the shipping; happily the incendiary Malays were dispersed by shot from the boats of the Cornelia, before a conflagration ensued. On the morning of the 23d of April, information was received that the sultan had fled from Palimbang on learning that the batteries of Borang were seized, and that the utmost confusion prevailed in the capital, many parts of which were a prey to rapine and assassination. To put a stop to this horrible state of things, and to prevent the massacre of the wealthy Chinese, which it was rumoured the sultan's adherents meant to perpetrate on the ensuing night, and whose property was to become the prize of the assassins, Colonel Gillespie meant to interpose a prompt relief. For this object, a resolute body guard was selected, consisting of 17 grenadiers of the 59th regiment, accompanied by Captain Bowen and Lieutenant Monday of the navy, Major Butler, Major Thorn, and Lieutenant Forrest. At their head was Colonel Gillespie. The rest of the troops was ordered to follow with all expedition. It was night before they reached old Palimbang. The canoe which contained its leader outstript in sailing the other two boats, and the report of a signal gun, fired by the enemy, increased the anxiety for their coming up, as the apprehension of some treacherous design was entertained. Horrid yells and shrieks in all directions broke around, while a conflagration illuminated a tract of country, stretching for upwards of seven miles on both sides of the river. By the exertions of the crews, the other two boats were brought up to the support of their friends. A scene of horror now was displayed, which would have subdued the courage of ordinary men, but called forth the characteristic presence of mind of Colonel Gillespie. To use Major Thorn's own words, "Romance never described any thing half so hideous, nor has the invention of the imagination ever given representations equally appalling with what here struck us in reality." Undaunted by hosts of armed men, Colonel Gillespie boldly stepped on shore, at the head of his devoted band, and marched with a firm step, through a multitude of Arabs and ferocious Malays, whose weapons steeped in poison, gleamed by the light of the torches. Huge battlements with massy gates, leading from one area to another, received the party, presenting the frightful spectacle of human blood still flowing and reeking on the pavement. The gates closed on its rear, and the blood-stained court-yards through which it was conducted, appeared as the passage to a slaughter-house. A Malay who approached the colonel through the crowd, while walking by his side, had a large double-edged knife secretly conveyed to him by one of his countrymen. At the moment, a flash of lightning darting through the tempest of the night, disclosed the weapon, while the assassin was endeavouring to conceal it in his sleeve. The colonel's eye caught the object, and regardless of the crowd, he ordered the Malay to be seized, and thus frustrated by his firmness of mind the murderous design. The weapon was found, but the Malay escaped. On arriving at the palace, a more dreadful picture of devastation and outrage was displayed. Here rapine and murder had gone hand in hand. Vivid flashes of lightning and peals of thunder conspired with the glare of the conflagration to give a peculiar character of awe to the scenes which caught the sight. The flames, which devoured every thing around, in spite of the rain which fell in torrents, threatened the spot where the band had sought a temporary shelter. The crackling of bamboos, the falling in of burning roofs with tremendous crashes, and the near approach of the flames amidst a hostile multitude and desperate assassins, gave to the situation of the party a most appalling prospect. An arduous task yet remained, to secure possession of the fort; and to perform this, the party was prepared to sell their lives as dear as possible, should an attack be made before the arrival of a reinforcement. The interior of the palace being carefully examined by torch light, all the entrances but one were barricaded. At this the grenadiers were stationed, and the strictest watch maintained. Soon after midnight, the party had the satisfaction of hailing the arrival of Major Trench with 60 men of the 89th regiment; and the remainder of the force under Colonel Macleod joined the little garrison early the next morning. Thus, by an act of unparalleled intrepidity, 17 British grenadiers, and the crews of two boats, with the officers above mentioned, were put in possession of a fort and batteries, mounting 242 pieces of cannon, without the loss of a man. A position which, by any other species of attack, must have risked the safety of the armament. The celerity of the movement, and the sudden arrival of the few British, whose numbers the panic of the enemy had magnified, caused the dispersion of the sultan's adherents, the prevention of their murderous project, and the relief of the town from the horrors of pillage. An American, in charge of a Chinese junk at Palimbang, gave a dismal recital of the storm about to burst that night, and which the interposition of the British had averted. This junk was marked as the first victim of its fury. The solemn deposition of the guilty sultan, by Colonel Gillespie, took place to the great joy of the people, and his brother was proclaimed in his stead. The object of the expedition being thus happily terminated, the force, with the exception of a garrison left behind, repaired to Samarang, where a fresh field for British valour was open in the heart of Java.

Critical situation of the party.

Conflagration.

Fort and batteries secured.

Deposition of the sultan.

The sultan of Mataram or Djoejoecarta, who had been intriguing the downfal of his last masters, still continued disposed to dispute the possession of Java with the British. The new Lieut.-Governor Raffles, and Colonel Gillespie, now commander of the forces in Java, repaired to Djoejoecarta, the sultan's capital, and after trying in vain to settle matters amicably, prepared for hostilities. The residence of the sultan, or Crattan, as it is called, is about three miles in circumference, surrounded by a broad wet ditch, with draw bridges, a strong high rampart with bastions, and defended by 100 pieces of cannon. In the interior are numerous squares and courts all strong and defensible; 17,000 regular troops manned the works, and an armed population of 100,000 men occupied the country for many miles round. The Dutch fort, within 800 yards of the Crattan, was calculated for little else than a military depot, and the fire from it was only intended to amuse the enemy while the force was concentrating. At length the troops having arrived, formidable from their intrepidity, not from their numbers, they were ordered into the fort, preparatory to the attack of the enemy's strong-hold. It was determined to carry the fortifications by assault, as the most prompt way of reducing the place, and of giving security to the colonies, threatened by the irruption of armed thousands at Bantam, Cheribon, Sourabaya, and other places, on the first signal. The different attacks being arranged by Colonel Gillespie, the works were escaladed, and carried with irresistible impetuosity. The troops were animated to heroic exertion by the cry of "death or victory" resounding through the ranks. In many places the enemy were dispersed by their own guns turned upon them. The sultan was compelled to surrender himself a prisoner, the cavalry and horse artillery being posted so as to intercept the fugitives. Hostilities having now ceased, the island of Java was restored to tranquillity and order, and has, we believe, been recently given over to the king of the Netherlands. See Stockdale's *Sketches of Java;* Sir George Staunton's *Account of the Embassy to China;* Barrow's *Voyage to Cochinchina;* Thunberg's *Travels;* Hamilton's *East India Gazetteer; Baptist Missionary Periodical Accounts,* No. xxvi.; Thorn's *Account of the Capture of Java;* and Brande's *Journal of the Arts and Sciences.*

Sultan of Djoejoecarta in arms.

Djoejoecarta taken by assault.

ICE is a transparent crystallised substance formed by the congelation of water when reduced to a temperature below 32° of Fahrenheit. As ice is generally produced by a very rapid congelation, it commonly occurs in an aggregated mass of separate crystals, the axes of which are turned in different directions. Under favourable circumstances, however, where the process of congelation has been slow, and the water exposed to no agitation, perfect crystals of ice are sometimes formed. M. Hassenfratz, M. Hericaut de Thury,* and Mr Scoresby, have observed crystals of ice that had the form of regular hexahedral prisms; and Romé de Lisle, M.

Crystals of ice.

---

* M. Hericaut de Thury observed the crystals of ice in the subterraneous glacier of Fondeurle, about two leagues to the east of Valence. The whole of the floor of the cavern was composed of hexahedral prisms of the most perfect transparency, of which the terminal surface presented striæ parallel to the faces of the prism, while the crystals which were found within the hollow stalactitical masses of ice, were partly triangular prisms, and partly hexahedral prisms; some of which were also striated on the terminal faces, and presented facets which replaced the terminal edges at the junction of the base and the prism. He was not able, however, to find any crystals with a complete pyramid.

D'Antic, and Mr Scoresby, have sometimes found them in the state of octohedrons, composed of two four-sided pyramids.

Optical properties of ice.

In examining the optical properties of ice, Dr Brewster found, that even large masses two or three inches thick, formed upon the surface of standing water, was as perfectly crystallized as rock crystal or calcareous spar, all the axes of the elementary crystals, corresponding with the axes of the hexahedral prisms, being exactly parallel to each other, and perpendicular to the horizontal surface.

This unexpected result was obtained by transmitting polarised light through the plate in a direction perpendicular to its surface. A series of beautiful concentric coloured rings with a dark rectangular cross passing through their centre, were thus exhibited. These rings were of the same nature as those seen along the axis of *Zircon;* for when they were combined with the rings produced by this substance, a system of rings was formed smaller than that which was produced by either singly; whereas, had they been of the opposite character, the rings produced by the combination would have been greater than one of the systems produced separately. Hence, ice belongs to the attractive class of crystals. The polarising force of ice is $\frac{1}{1111}$, that of rock crystal being $\frac{1}{180}$. Its refractive power is 1.307 less than that of water, and its specific gravity is also less than that of water. For an account of the chemical laws on which the congelation of water depends, see CHEMISTRY.

History of the polar ice.

Under the article COLD, and also under GREENLAND, some of the phenomena which accompany the formation of ice in polar regions are briefly mentioned. Their history, however, is sufficiently important to require a minute description, on account of the great scale on which congelation is effected, the variety of the appearances presented, the striking grandeur of some, and the singularity of others, together with the suggestions which some known circumstances concerning it afford for the prosecution of interesting objects.

The appearances which the ice presents in its outline, especially when existing in a detached state, are diversified; and, being of great interest to mariners who navigate the polar seas, they are designated by distinct terms with as much familiarity as the varieties of form which occur on land.

Fields of ice.

A continued sheet of ice, so extensive that its ulterior boundary cannot be seen from the mast-head of a ship, is called a *field.*

Fields are formed from ice which is in the first instance fixed. They owe their origin to a process of congelation on the surface of the ocean, to which the vicinity of land is not, as some have supposed, necessary. This process takes place both in a rough and in a smooth state of the surface, when the temperature is sufficiently low. It requires a temperature considerably inferior to the freezing point of fresh water, as the force must be sufficient to surmount the attraction of the salt for the water which holds it in solution, for more or less separation always takes place: the ice formed under these circumstances, never affords water of equally strong impregnation as the original water of the ocean.

Progress of congelation.

On a rough surface, this process begins with the formation of detached crystals, called by the sailors *sludge,* which resemble snow immersed in water without undergoing liquefaction; by the union of the crystals, and the accumulation of the sludge, the surface is rendered smooth. The continued sheet now formed is soon broken into fragments of about three inches in diameter; these again coalesce and form a continued texture of a stronger kind, which, in its turn, is broken into masses of much larger size. These are rounded at the edges by mutual attrition, and receive the name of *pancake ice.*

In sheltered situations and in still weather the congelation goes on more regularly, and to appearance more rapidly. The thin sheet formed in the first instance, receives accessions to its thickness from beneath. In twenty-four hours of keen frost it often acquires a thickness of two or three inches; and in less than two days is strong enough to bear the weight of a man. This is termed *bay ice,* from being formed in sheltered bays. That which is of older formation is distinguished into two kinds, according to its thickness, being called *light ice* when from a foot to a yard thick, and when above a yard *heavy ice.*

Some fields of ice are so smooth in their surface, so transparent in their texture, and so exactly similar to the ice formed on fresh lakes, that it has been believed scarcely possible that they should be produced by the freezing of the ocean, and they have been considered as owing their origin, at least in part, to the freezing of rain or melted snow, which had settled on a flat surface of young ice, encircled by a ledge of older ice, which retained the water like a cup.

Floes.

Loosened pieces, which are smaller than fields, but still of very large dimensions, are called *floes.* Pieces much smaller, detached from the angles of larger ones, and floating in a congregated state, are called *brash ice.*

Brash ice.

Drift ice.

Ice of any form or size, floating in a state sufficiently loose to allow a vessel to sail freely among it, is called *loose, open,* or *drift ice.*

Packs and patches.

A number of large pieces in close contact, forming a congeries which cannot be seen over from a mast head, are called a *pack.* A similar congeries, which can be seen over, is called a *patch.* When a congeries of either kind is of an oblong shape, it is called a *stream* of ice.

Hummocks.

A protuberance, considerably elevated above the common surface of flat ice, is called a *hummock.* Hummocks often attain the height of thirty feet or upwards. They are sometimes formed by fields of ice crushing each other, so that large pieces, separated from the margin, are raised on edge, or a numerous wreck is accumulated on the top of a field. Hummocks are generally near the margin, but sometimes they extend to the middle of a field, showing that their origin is sometimes different from that now described. They communicate to the ice a variety of fanciful shapes, and render the whole appearance of it highly picturesque.

Calves.

When the effect of concussions of pieces of moderate size is to accumulate such masses above a comparatively thin *floe,* that the surface of the latter is depressed beneath that of the water, this part is called a *calf.* Some of these *calves* are sufficiently deep to allow a vessel to sail over them. But it is dangerous to approach them, their depth being uncertain and unequal; and when they rub freely against the superincumbent pieces, they often become so far detached that their buoyancy raises them to the surface, and their momentum during a change of situation is sufficient to stave the timbers of a vessel, or reduce it at once to a wreck. Sometimes even a gentle heaving motion of this sort, by raising one end of a vessel, immerses the other end, to the imminent danger of precipitating it in that direction to the bottom.

Concave sinuosities in the border of a large mass of flat ice are called *bights*. They often afford a convenient refuge to ships, but sometimes they give occasion to detentions of the most inconvenient and dangerous kind.

Effects of a ground swell.

We have now to notice some changes of a grander and more terrific description, to which the ice is subjected. That powerful tendency to undulation of the surface, communicated by the agitation of the adjoining liquid surface of the ocean during a continued storm, which is denominated a *ground swell*, sometimes produces a sudden disruption of extensive fields. The ice, when thin, accommodates itself to the surface by bending; but, when several yards in thickness, it refuses to yield beyond a certain extent, and is broken into pieces with dreadful explosions. The best account that we know of the appearances presented on such occasions is given by a party of Moravian missionaries, who were engaged in a coasting expedition on the ice along the northern shore of Labradore, with sledges drawn by dogs. They narrowly escaped destruction from one of these occurrences, and were near enough to witness all its grandeur. We extract it from the recent interesting compilation of the Rev. Dr Brown, on the *History of the Propagation of Christianity*, vol. ii. p. 51. "The missionaries met a sledge with Esquimaux turning in from the sea, who threw out some hints that it might be as well for them to return. After some time, their own Esquimaux hinted that there was a ground swell under the ice. It was then scarcely perceptible, except on lying down and applying the ear close to the ice, when a hollow disagreeable grating noise was heard ascending from the abyss. As the motion of the sea under the ice had grown more perceptible, they became alarmed, and began to think it prudent to keep close to the shore. The ice also had fissures in many places, some of which formed chasms of one or two feet; but, as these are not uncommon even in its best state, and the dogs easily leap over them, they are frightful only to strangers. As the wind rose to a storm, the swell had now increased so much that its effects on the ice were extraordinary and really alarming. The sledges, instead of gliding smoothly along as on an even surface, sometimes ran with violence after the dogs, and sometimes seemed with difficulty to ascend a rising hill. Noises, too, were now distinctly heard in many directions like the report of cannon, from the bursting of the ice at a distance. Alarmed by these frightful phenomena, our travellers drove with all haste towards the shore; and, as they approached it, the prospect before them was tremendous. The ice having burst loose from the rocks, was tossed to and fro, and broken in a thousand pieces against the precipices with a dreadful noise; which, added to the raging of the sea, the roaring of the wind, and the driving of the snow, so completely overpowered them, as almost to deprive them of the use both of their eyes and ears. To make the land was now the only resource that remained, but it was with the utmost difficulty that the frightened dogs could be driven forward; and, as the whole body of the ice frequently sunk below the summits of the rocks, and then rose above them, the only time for landing was the moment it gained the level of the coast,—a circumstance which rendered the attempt extremely nice and hazardous. Both sledges, however, succeeded in gaining the shore, and were drawn up on the beach, though not without great difficulty. Scarcely had they reached it, when that part of the ice from which they had just escaped burst asunder, and the water rushing up from beneath instantly precipitated it into the ocean. In a moment, as if by a signal, the whole mass of ice for several miles along the coast, and extending as far as the eye could reach, began to break, and to be overwhelmed with the waves. The spectacle was awfully grand. The immense fields of ice rising out of the ocean, clashing against one another, and then plunging into the deep with a violence which no language can describe, and a noise like the discharge of a thousand cannon, was a sight which must have struck the most unreflecting mind with solemn awe. The Brethren were overwhelmed with amazement at their miraculous escape, and even the pagan Esquimaux expressed gratitude to God for their deliverance."

Icebergs described.

Ice in that elevated form which is called the *iceberg*, demands particular attention. This term is applied to such elevations as exist in the vallies of the frigid zones; to those which are found on the surface of fixed ice; and also to ice of enormous thickness and stupendous height in a floating state. The vallies of West Greenland are filled with icebergs to an extent never yet explored. The seven icebergs in the vallies on the west coast of Spitzbergen, were supposed by Mr Scoresby, when seen by him, to present a perpendicular front 300 feet high. Their green hue, and glistening splendour, exhibited a pleasing variety, and added a richness to the prospect by the contrast which they presented with the magnificence of the neighbouring snow-covered mountains. From these icebergs enormous overhanging masses are sometimes detached by their own weight, as from the glaciers of the Alps. This separation is aided by a softness of cohesion which they acquire in the thawing season; and it is also believed that quantities of water pent up within them exert, in the act of freezing, an expansive force, which produces disruption. Masses of this kind, in a floating state, are most plentiful in Baffin's Bay, where they are sometimes two miles long, and two-thirds of a mile broad, bristled with varied spires, rising more than 100 feet above the surface, while the base extends 150 yards beneath it. Icebergs of an even surface, elevated 30 yards above the sea, and five or six square miles in area, are very common. Those of East Greenland are of inferior size. The largest that Mr Scoresby ever saw was 1000 yards in circumference, flat on the summit, and nearly 20 feet above the level of the sea. This difference probably arises from the more sheltered situation of the large bays of West Greenland.

We have reason to believe that many icebergs are formed at a distance from any land. This appears from the account which Muller gives of an expedition made, in the year 1714, by Markoff a Cossack, after he had been foiled by drift ice in an attempt to explore the ocean to the north of Russia. This adventurous person set off with a party from the coast of Siberia at the mouth of the river Yani, in North Lat. 71°, in the month of March, to travel on the surface of the ice to the north pole in sledges drawn by dogs. He proceeded for seven days till he reached the 78th degree, when his progress was impeded by ice elevated into prodigious mountains, from the summits of which he could discern nothing but mountainous ice to the northward. He therefore returned, and, after some hardships and losses, reached the coast of Siberia on the 3d of April, having in 19 days travelled 800 miles. To what extent these masses may be detached during summer in regions nearer the pole than any that have hitherto been navigated, we cannot determine; but it is not improbable, that from this source many of the loose icebergs are derived which are found floating to the west of the islands of Spitzbergen. It is probable that many are also formed on the eastern coasts of these islands, which are more favourable to such a process. But the numbers of these enormous masses that come by Davis's Straits are by far the greatest, and the coast of Newfoundland is often crowded with them. They gradually dissolve as they move to the southward; but some have been found in Lat. 40°, 2100 miles from their source.

These lofty masses are formed partly by the accumulation of drifted snow first slightly softened by the summer heat, and acquiring an augmented solidity by a subsequent process of congelation. It is probable that their high peaks receive accessions from the falling moisture, which is more readily congealed than that which lies lower, the temperature being lowest at the highest elevations. We mentioned under the article COLD an ingenious conjecture of Professor Leslie, that they attained their great height by the deposition of hygrometric water from the air ascending from the surrounding ocean in a manner analogous to those rising peaks of ice which are formed in the congelations produced in the ingenious process for freezing water by its own evaporation, of which that philosopher is the inventor. But we may be allowed to suspend our entire acquiescence in this opinion till it is ascertained how far these formations themselves may arise from a cause totally different, viz. the elevation of moisture by the capillary attraction of the previously formed crystal. We know that this is the mode in which similar peaks are formed during the leisurely crystallization of certain neutral salts by evaporation. If a solution of muriate of ammonia is left for some days to evaporate spontaneously in a glass, appearances of the same kind are presented.

Their occa- ional uti- ty.

The shelter created by icebergs is often highly useful to the whalers, by protecting them from gales, as well as from the concussions of drift ice, as the latter moves more quickly, requiring a shorter duration of the wind in one direction to attain its utmost velocity. The ships are sometimes moored to the icebergs for security; but this situation is not without its dangers. The masses are sometimes so nicely balanced as to be easily overturned. They sometimes catch the bottom in places comparatively shallow, though still of great depth, and the effect of the concussion is to detach large pieces from them, or to cause the whole mass above water to plunge forward under the surface, and the vessel moored to them is staved and wrecked. The same effect is produced by the rising of immense calves. These occurrences sometimes happen when the ship rides at a distance of 100 yards from the emergent part. The motions are indeed of so tremendous magnitude, that a vessel is sometimes lost by the vast waves and whirls which they occasion, which overwhelm every smaller object within a considerable distance of the rolling mountain. Icebergs often prove useful by supplying the ships with fresh water, which is found collected in large wells on the surface, and is let down into the vessel by a cylindrical piece of canvas called a *hose*.

utline of e fixed e.

The irregular outline of the fixed polar ice, and the changes to which it is subjected in the course of years, are highly interesting. Before the 15th century, the eastern coast of West Greenland was free from ice in summer, and could be freely approached by ships. After a considerable trade had for 400 years been carried on between Iceland and that country, which was inhabited by a large and flourishing colony, the polar ice suddenly exceeded its former limits, launched down in a direction nearly parallel to the coast as far as the southern Cape, and barricadoed the whole coast in such a manner as to render it ever since inaccessible. The fate of the colony is unknown. If the increased severity of the climate was insufficient to destroy it, this effect was inevitable from the destruction of all the resources on which it depended. The mass of ice lying between Old or West Greenland and the northern part of Russia on the east, though varying in different seasons, presents a striking uniformity in its general outline. After doubling the southern promontory of Greenland, it advances in a north-eastern direction, half enveloping Iceland in close seasons, till it reaches the small island called John Mayne's Island, which it frequently encloses. It then trends a little more to the eastward, and intersects the meridian of London in the 71st or 72d degree of latitude. Having reached the longitude of 6, 8, or 10 degrees east in the 73d or 74th degree of latitude, it suddenly stretches to the north; sometimes proceeding on one meridian to the latitude of 80°, at others forming a deep sinuosity, extending only two or three degrees northward, then south-easterly to Cherry Island; it then assumes a straight course a little south of east, till it forms a junction with the coast of Nova Zembla.

On the whole, the tendency to a fixed state of the ice is greatest on the eastern sides of land. These are rendered peculiarly cold, from the westerly winds having had their temperature reduced by blowing over the eternal snow and ice of the continents. These winds are in their origin warmer than the east, as they generally originate in southerly situations; whereas the east winds, originating in the north, are less liable to a reduction of temperature in passing over a frozen continent. Thus the eastern shores are exposed to all the original coldness of the east winds when they blow, and to an additional coldness acquired by the west winds; while the western shores are wafted by the west winds in their mild state, in which they keep up a liquefying process, a quality which they lose after traversing the land. It is well known, that south-west and north-east winds are more common in the northern hemisphere than the north-west or the south-east. Winds that blow directly from the west tend to produce a perpetual extension of the ice; but the south-west winds give that form to its boundary which we find it actually to possess, *i. e.* a line stretching to the north-east. But why, at one period, the coast should for centuries be free from ice, and at another period be perenially lined with it, is one of those phenomena in the changes of climate, for which, like many others in meteorology, we cannot account. For an illustration of the circumstances now stated, we refer to the meteorological Essays of Mr Dalton. See also our article METEOROLOGY. The form of the outline of the ice varies however according to the direction and force of storms and currents.

Whale fishing seas of Spitzbergen.

The deep bay formed by the boundary of the ice to the west of Spitzbergen, is the only track for proceeding to the fishing latitudes in the north. In close seasons, the ice at the extremity of this bay is so close, that the vessels cannot advance beyond the 75th or 76th degree; but in open seasons, they have an uninterrupted navigation along the western coast of Spitzbergen to Hackluyt's Headland, the north-western angle. An open channel extends in such seasons from 20 to 50 leagues in breadth, to the latitude of 79° or 80°, gradually approaching the coast, till it effects a junction with its northern extremity by a curvilinear head. It is only in this open part, that they can proceed sufficiently far to the north to find the whales. These animals, of stupendous size, but timid in disposition, prefer these places, as affording the most secure retreats, enabling them to dive beneath the ice out of the reach of danger, and to return to the open part to respire. It is in the 78th and 79th degrees of latitude that they occur in greatest number. At the southern part of Spitzbergen, there is, at the bottom of the bay called *the whale fisher's bight*, a barrier of compact drift ice, mixed with bay ice, stretching from the fixed ice on the west to that on the east, and from 20 to 40 leagues in breadth. This always exists in the early part even of open seasons, and to find their way across this barrier, is with mariners one principal object of anxiety and exertion. For this purpose, every advantage is taken of those openings in the ice, which are expressively called *veins of water*. When the wind is fair, they set all possible sail in order to accomplish it speedily, and yet find it necessary to be on their guard against the dangers which surround them from pieces of floating ice, dangers which of course are augmented in proportion to the velocity of a ship's motion. These difficulties occur in the month of April; but by the end of June the ice is dispersed, and a safe return afforded, which could scarcely be obtained if it continued equally prevalent, as the fogs, which obstruct the view at the end of the season, would prevent them from seeing their way through similar obstructions. In sailing to the north, it is of importance to anticipate the separation of the ice, in order to catch the best season for the fishery.

Great and unexpected changes often take place in the manner in which the drift ice is collected. It frequently happens, that a ship is completely beset, and unable to move in one direction or another, and next day, without apparent cause, the ice is completely dispersed, and an open sea presented on every side. A tendency to separation always takes place in the drift ice during a calm. The changes to which the local situation of a ship is on such occasions subjected, are not less surprising. Two ships surrounded with close ice a few furlongs apart, have sometimes been in a few days separated to a distance of several leagues, though no apparent change took place in the continuity of the pack. Bay ice sometimes proves beneficial to the whaler, by imbedding the ship, and averting that danger which arises from the unequal shock produced by the brunt of the heavy ice. But it is in other respects extremely troublesome, as it is often the means of besetment, and thus the primary cause of the greatest calamities. A sheet of it a few inches in thickness, is sufficient to render a ship immoveable. If, under these circumstances, it is too strong to be broken by a boat, recourse is had to the laborious operation of sawing it.

The general tendency of the loose ice in the neighbourhood of Spitzbergen, is to drift to the south-west, towards Iceland and Cape Farewell in West Greenland. When we consider the obstacles encountered in the navigation of the northern seas, which are not more exempt than others from stormy weather, and find that these fishing voyages are attended with so much average security, we have a striking exemplification of the adventurous spirit of man, and of the power of art in surmounting difficulties of the most threatening kind. A combination of thick weather, a stormy gale of wind, and a tempestuous sea, crowded with detached pieces of ice, each of which is enveloped in a thick spray raised by the dashing of the waves, presents one of the most terrific navigations that can be conceived.

The ice blink.

The phenomenon called the *ice-blink* is worthy of our attention. It is a lengthened stripe of lucid whiteness in the sky, bordering the visible horizon, which often affords a beautiful and perfect map of the ice, 20 or 30 miles beyond the limit of direct vision. This even serves to shew to the experienced observer the exact kind of ice, whether field or packed, which occurs in that direction.

Plan for travelling over the polar ice.

Mr Scoresby has projected a plan for surmounting the obstacles opposed by the ice in a visit to the north pole, by travelling over the surface of it in the manner already mentioned as having been put in practice by Markoff. This is detailed in an intelligent and ingenious paper, read before the Wernerian Society, which contains much information relative to the polar ice, and to which on this subject we have been principally indebted. Access to it previously to publication has been most obligingly furnished to us by Professor Jameson, the president of that Society. Of that plan it would be out of place to give any particular account. It will be inferred from the circumstances already mentioned as having occurred to Markoff, that, though not impracticable, it must be extremely precarious, and that those who engage in it, must be prepared for total disappointment after the most Herculean exertions. Yet it is worthy of remark that, if no obstruction arose from the form of the surface of the ice, an expedition undertaken from the northern coast of Spitzbergen to the north pole and back, would exceed that actually performed by Markoff only by 250 miles. Some important information, in reply to a series of queries directed to the elucidation of this subject, is given by Colonel Beaufoy, in Dr Thomson's *Annals of Philosophy* for May 1817. It was obtained from Russian fishermen who had wintered at Spitzbergen. The tendency of the accounts given by them, is to impress us with the difficulty of such an undertaking, both as arising from the great inequality of the surface of the ice, in so far as could be inferred from observations made in that part of the world, and from the storms of wind and snow, which are represented as extremely frequent. An answer to an additional query, however, is still wanted: Is there any period of the winter at which a few weeks of fair and calm weather may in general be depended on? Or are there any meteorological appearances from which such a track of weather may be occasionally predicted? One interesting practical inquiry is suggested by the degree of success obtained by Markoff. Might not an attempt be made to explore by similar means the site of the ancient colony of West Greenland?

Antarctic ice.

Of the ice of the southern hemisphere we have less particular accounts. But we know that ice extends to a much greater distance from the south pole than from the north. The 80° of north latitude is almost annually accessible at one part to navigators, and has occasionally been exceeded. The 73° or 74° may be attained in the closest summers. But the *ne plus ultra* of the antarctic hemisphere is the 72°, *i. e.* 600 miles short of that of the arctic: The nearest approach made to the South pole being 1130 miles, and to the North pole 510. Icebergs and floating ice of all forms abound in the southern seas, and present similar appearances to those found in the northern.

Ice at the bottom of the water.

We shall now take notice of one circumstance in the history of ice which is seldom particularly described, viz. that it is found forming at the bottom of water, even on a large scale, while the surface remains liquid. This seems contrary to what might be expected from the order which takes place in the successive reduction of temperature in different parts of the same portion of water, as well as from the comparative specific gravities of water and ice. The facts are well ascertained, as occurring in Germany, in Great Britain, and in North America. In Germany two kinds of ice are described as formed in that situation: one which is called *sichl-eis*, is the first that is formed at the beginning of a severe frost, and immediately rises to the surface in small grains, similar to hail. The other, from retaining its situation longer, is more commonly observed and better known. This is called in Germany *grund-eis*. In Scotland, where it is not uncommon, it is called *grund-grue*, i. e. "ground-grown." Men of science, not having attended to these phenomena, have considered them, when accidentally met with, as extraordinary. It has happened, when they were in quest of something else, that they have found at the bottom of a river a sandy mass agglutinated in a manner which they did not comprehend, till they found that the cementing medium was ice. At other times they have been struck with great surprise on finding gravel, earth, or mud, mixed with ice on the surface. But such phenomena are familiar to the fishermen and boatmen on some of the northern rivers, particularly the Elbe. They sometimes find it difficult to fix their anchors, on account of the smoothness which the ice imparts to the bottom. When taken up, the anchors are sometimes coated with ice, and at other times it forms on them in such quantities, as to raise them to the surface by its buoyancy. Ice, instead of fish, is not unfrequently brought up with the fish-hooks. The sluices and flood-gates are sometimes rendered immoveable by the ice formed at the bottom. It often acquires a great thickness before it rises, and then brings up with it not only earth and gravel, but stones of large size. We are told, on credible authority, that in the Elbe the stones to which buoys had been fixed as marks of the dangerous shallows, have been brought to the surface by the *grund-eis*, and removed to a different part of the river. On the margins of lakes numerous new fragments of rock have been found on the subsiding of frost, which had been brought up in this manner from the middle and floated to the edge. Some species of bottom are more favourable to this process than others: sand and gravel are more so than solid rock. M. Brauns, a Hanoverian, after consulting with much care the best sources of information, learned that in the northern seas, traces both of *sichl-eis* and *grund-eis* were found where the depth of the water was 108 feet. In the Baltic alone it was found at depths still greater. One reason why these phenomena are seldom observed is that ships return before the setting in of the strong winter frosts. Mr Knight, in the *London Philosophical Transactions* for 1816, thus describes the phenomena as they occurred under his own observation, and at the same time delivers his opinion of their physical cause. "I first witnessed the existence of ice in the bottom of the water in the river Teme, which passes near my residence in Herefordshire, in the last winter. In a morning which succeeded an intensely cold night, the stones in the rocky bed of the river appeared to be covered over with frozen matter, which reflected a kind of silvery whiteness, and which, upon examination, I found to consist of numerous frozen spicula crossing each other in every direction as in snow; but not having any where, except very near the shore, assumed the state of firm compact ice. The river was not at this time frozen over in any part; but the temperature of the water was obviously at the freezing point, for small pieces of ice had every where formed upon it on its more stagnant parts near the shore; and upon a mill-pond just above the shallow streams, in the bottom of which I had observed the ice, I noticed millions of little frozen spicula floating. At the end of this mill-pond numerous eddies and gyrations were occasioned, which apparently drew the spicula under water, and I found the frozen matter to accumulate more abundantly on such parts of the stones as were opposed to the current where that was not very rapid. On some large stones near the shore, of which parts were out of the water, the ice beneath the water had acquired a firmer texture, but appeared from its whiteness to have been first formed of congregated spicula, and to have subsequently frozen into a firm mass, owing to the lower temperature of the stone or rock."

Theories on the subject.

The theory here given by Mr Knight falls short in accounting for the facts which he himself observed; for, by supposing the spicula to have been formed at the surface, and afterwards precipitated by the tumbling motions of the water to the bottom, it does not contain an explanation of that congelation which must go on at the bottom itself before the spicula can adhere to the stones. On other occasions it is formed in places where the motion is far from being sufficient to send the floating crystals to the bottom. It is also to be remembered that, instead of such spicula as Mr Knight describes, smooth and compact ice is found in these situations. We would therefore observe, that water, when reduced to 32°, and then deprived of an additional portion of caloric, though it has a tendency to freeze, yet experiences in this respect different degrees of facility according to certain circumstances. One of these is the presence of certain solid points or rough surfaces. Hence water reduced to 26° without freezing, immediately freezes when a crystal is dropt into it, and the ice forms first upon the crystal itself. Agitation also seems to influence it. Water, when left quite stagnant, may remain liquid, and be immediately frozen by a gentle shaking. But a great degree of agitation while it is cooling seems to retard congelation, and always prevents it from proceeding with regularity. Now it appears to us, that in whirls and eddies, the water at the surface loses a certain portion of caloric, and receives a tendency to congelation, which however is resisted by the motion to which it is subjected, and may be promoted in another place by a slight additional aid from an external cause. The motion, indeed, while it prevents the freezing of the surface, assists that process at the bottom by accomplishing the reduction of the whole body of water to the freezing temperature. It is well known that the temperature of greatest contraction and specific gravity of water is somewhere above the freezing point, about the 40° of Fahrenheit. While higher than 40°, a reduction of the temperature at the surface, by increasing the specific gravity, produces a sinking of the superficial portion, and an intermixture with that which is beneath. But, after it has reached the 40th degree, a farther reduction of temperature, instead of contraction, produces an expansion; and the water retains its situation, unless operated on by some other force. While it is perfectly still, therefore, it remains at 40° at the bottom, while at the surface it is at 32°, and in that part the process of congelation goes on, the mere conducting power of water requiring a long time to effect an equalization of temperature. The difference of specific gravity, however, between water at 40° and at the freezing point is not great, and a very slight motion is adequate to produce a thorough intermixture, and consequent extension of the freezing temperature through the whole. When this is effected, and at the same time the congelation resisted by the motions of the surface, it is promoted by the nature of the substances at the bottom. The varieties in the qualities of different substances in this respect, as ascertained by experiment, are curious. Hair, especially boiled horse hair, wool, chaff, moss, and the bark of trees covered with lichens, are found to promote the formation of ice in a higher degree than any metals. Of the latter, copper, brass, steel, and above all tin, have ice formed on them sooner and more abundantly than iron. Polished stone and earthen-ware attract very little. On wax, resins, pitch, silk, leather, and wood deprived of its bark, it is seldom or never found. On the bottoms of boats, however, incrustations have been found, which have been evidently formed of the *sichl-eis*.

This process requires a powerful frost. Hence it appears comparatively seldom in the more temperate countries. Yet it is described by M. Desmarest as having occurred in the Rhone and the Seine. The laws by which it is regulated are worthy of a more minute experimental investigation than they have hitherto received.

ICELAND.

Iceland.

ICELAND, is a large island situate on the verge of the Arctic Ocean, between the 63° and 67° of north latitude, and the 12° and 25° of longitude west from Greenwich.

History.

This island was discovered about the year 860 by a Norwegian pirate, named Naddodr, who was accidentally driven upon the coast while on a voyage to the Faroe islands. A few years afterwards a Swede, *Gardar*, succeeded in circumnavigating the island, and gave it the name of Gardarsholm. Its present name was given to it by Floke, a famous pirate of those times, who remained two years, during which he explored most of the southern and western coasts. The country was colonized in the year 874, from Norway; the subjugation of which, by HAROLD the fair-haired, had produced much discontent among the petty states which he reduced. The leader of the emigration from Norway was named *Ingolf*, who, with his kinsman *Hiorleif*, went to Iceland in the year 870, and made arrangements for the settlement. It is asserted by some of the Icelandic historians, that there were actual settlements in the island before this period; but this seems improbable. The first of the Norwegian visitors found, on some parts of the coast, wooden crosses, and implements, from which it is inferred that those who had preceded them were Christians. In the *Landnama Bok*, which is among the earliest of the Icelandic historical records, it is stated, that, among other things, writings in the Irish language were found. The statements on this subject are so various, that it is impossible to form any probable conjecture on the point in question.

The colony first settled in the south-western part of the island; and the spot where the town of Reikiavik now stands was chosen, on account of the result of a superstitious observance, which guided many of the settlers in the choice of their future places of abode. When Ingolf approached the shores of Iceland, he threw into the sea the door of his former habitation in Norway, and having found it cast on the beach at Reikiavik, he there fixed his station. In the course of half a century, the coasts of this remote country were well peopled; and in the *Landnama Bok*, already mentioned, which contains minute details of the spreading of the colonies, we find several names of Scotch and Irish families who came over and settled.

At first, every body of emigrants remained under the influence of a leader, who parcelled out the land to his followers. But this feudal arrangement was soon found inconvenient, from the contests which arose for possessions claimed by the various petty chieftains. By common consent, a new system of government, which included the whole country, was settled in the year 928. The island was divided into four provinces, superintended by an hereditary governor. The southern and western provinces were subdivided into three prefectures, the northern one into four, and the eastern into two. The authorities over these were also hereditary. There were still more subdivisions, called *Hreppar*, in each of which five officers were appointed, men of property and respectability, whose care it was to keep peace and good order, and to manage the concerns of the poor in their respective districts. The proceedings of the superintendants of districts were under the cognizance of the prefect and his deputies, who met once a year; from whom there was an appeal to the provincial court; and finally, to the supreme assembly of Iceland.

This great assembly was held annually on the shores of the lake called Thingvalla, from the name of the assembly *althing*, which is derived from *al*, all, and *thing*, a court of justice. A president was chosen, with the title *Laugman*, or administrator of the laws, and was invested with all the symbols of dignity and power. It was his province to interpret the laws, and pronounce sentence; and his authority, though dependent on the will of the states, was often continued for life.

Such is an outline of a constitution settled without any contention, to which may be referred the arrangements in the government of almost every modern state in Europe. The Hreppstiores have the same jurisdiction with our justices of the peace, and the prefects of our sheriffs. The provincial assemblies resemble our quarter sessions, and the supreme assembly our parliament. For a minute account of the Icelandic commonwealth, the reader may consult the *Crymogæa* of *Arngrim Jonas.*

The code of laws adopted with this new form of government, and which were progressively amended by the assembly, is a remarkable example of the genius of the people of this age. To enter into a minute examination of it would far exceed the limits prescribed to this article, and we must refer to the works enumerated at the end. With respect to the criminal laws, corporal punishment was rarely inflicted; the atonement for almost every offence being a fine, extended according to circumstances, even to the confiscation of the whole property of the criminal. The trial by jury, though not enacted, was sometimes resorted to in particular cases.

"The constitution thus adopted by the Icelanders, (says Dr Holland, in his Introduction to Sir George Mackenzie's *Travels in Iceland,*) was preserved with little change for more than three centuries; during which period the records exist of thirty-eight laugmen, who in succession sustained the executive power. Were it allowed to apply the term to a desolate island on the confines of the Arctic circle, this might be called the Golden Age of Iceland. Secured by physical circumstances from the ambition of more powerful states, an efficient government and well directed laws provided for the people all the advantages of justice and social order. Education, literature, and even the refinements of poetical fancy, flourished among them: like the aurora borealis of their native sky, the poets and historians of Iceland not only illumined their own country, but flashed the lights of their genius through the night which then hung over the rest of Europe. Commerce was pursued by the inhabitants with ardour and success; and they partook in the maritime adventures of discovery and colonisation which gave so much merited celebrity to the Norwegians of this period. Many of their chiefs and learned men visited the courts of other countries, formed connections with the most eminent personages of the time, and, surveying the habits, institutions, and arts of different communities, returned home fraught with the treasures of collected knowledge. Nor was there among the Icelanders of this period an extinction of the elevated spirit, common to their forefathers and to the age. The Sagas, or tales of the country, afford many striking pictures of that high feeling of honour, and of those deeds of personal prowess, which were cherished by the disposition of the northern nations, and which refused not to exist even in this remote and desolate region."

Literature.

The colonization of Iceland having been undertaken by men of rank and education, literature was carefully cherished among them; and their language, the Gothic, was preserved in its utmost purity. The ancient mythology of Scandinavia afforded ample scope for poetic fiction and ornament; and the desolate region of Iceland, the gloominess of which was only interrupted by natural phenomena the most awful and tremendous, gave a range to the favourites of the muse, which imagination could scarcely exceed. The taste for poetry thus imbibed by the first inhabitants, descended to their posterity; and to this day it is no small part of the amusement of the people, during the darkness of winter, to recite the legends of former times. Nor was the fame of the Icelandic Skalds * confined to their own country. Foreign potentates cherished them in their courts, and munificently rewarded them for singing their praises.

The character of the Scandinavian poetry of this age was stamped by metaphorical obscurity. Resemblance could not be too distant, nor too fanciful, for a northern poet; and the habitual use of metaphor occasioned the adoption of phrases as familiar, which, to those unaccustomed to the style, appear extravagant and unnatural. This obscurity does not however extend through the whole of Icelandic composition, which, particularly in the relation of common events, is often exceedingly simple. Rhyme was rarely employed; and the harmony of the versification seems to have depended on alliteration, and the arrangement of particular sounds adapted to the nature of the language. Thus there was opened a broad field for the exercise of skill, as well as imagination; and the frequent contests in versification brought the Scandinavian poetry to be an art of the most refined nature. Having more leisure, the Icelandic poets excelled; and, from catalogues still preserved, we find, that of the Skalds who flourished in Sweden, Denmark, and Norway, the majority of the whole number were Icelanders.

The most celebrated and valuable remnant of northern poetry is the Edda, a work designed as a common means of education in the favourite pursuit of this extraordinary people. The Edda appears to have been composed at different times, and by different writers, about whom there has been much controversy. There are two different works which bear this title, the Edda of Sæmund, and that which bears the name of Snorro Sturlesen, to whom it is ascribed. The first or ancient Edda consists of a number of odes, of which the Voluspa, or prophetess of Vola, and the Hávámal, are the most important. The former is a short and obscure digest of the Scandinavian mythology; and the latter consists of moral precepts, supposed to have been delivered by the god Odin. They are attributed to Sæmund Sigfuson, an Icelander, who was born in the year 1056; and so eminent, as to have acquired the denomination *Frode,* or learned. The other Edda is more perfect, and better adapted to the object of instruction in the art of poetry. The first part contains a view of mythology in the form of a dialogue, in which the attributes and actions of the deities, and other events, are explained. The second part is a collection of synonymes, epithets, and prosodaical rules, in which the errors of style, and the varieties of metre, are carefully pointed out.

Sagas.

The historical writings of this age do more honour, perhaps, to Iceland, than the cultivation of poetry. Of these, the Sagas, which are of a mixed character, blending, to a certain extent, fiction with authentic narrative, are exceedingly valuable. They possess great variety, some detailing particular events relating to politics or religion, some the history of a particular family, and others the biography of eminent individuals. As might be expected, many of these narratives are tedious; but in many are to be found examples of simplicity, which carry the reader back to the times in which the actors lived, and insensibly lead him to consider himself not an indifferent spectator.

The Sagas have elucidated the history and antiquities of the north in an eminent degree; but the regu-

---

* The word *skaldr*, or skalds, signifying bards, is probably derived from *skiael*, wisdom; whence the English word skill.

lar historical writings which have come to us from the Icelanders are yet more valuable. The *Annales Oddenses* of Sœmund Frode; the *Landnama Bok*; the Chronicle of the Kings of Norway, by Snorro Sturleson; and numerous other works, testify the abilities and correctness of the writers. Besides poetry and history, mathematics and mechanics were cultivated; and jurisprudence formed an important study. Travellers penetrated into Asia and Africa; and the maritime adventures of the Icelanders prove that attention was paid to astronomy and geography. Philology was not neglected, and the most celebrated Roman authors were familiar to all the learned men. The Greek language was not much cultivated.

Before the establishment of Christianity, which took place in the year 1000, the Runic was the only character in use; but more seems to have been trusted to memory than to writing. With Christianity, the Roman characters were introduced, and a new incitement was thus given to education, and every literary pursuit. The first school was established by Isleif, the first bishop of Skalholt, about the middle of the 11th century; and soon after three others were formed in different parts of the island. In these the youth were taught to read, write, and compose in their own language, and initiated in the classics and in theology, to which last particular attention was given.

Christianity established.

The establishment of Christianity was not the least remarkable event in the early history of Iceland, since it was effected in a manner which displayed, in a striking manner, the genius and government of the people. Frederic, a bishop from Saxony, began to preach the Christian doctrines in the year 981; and the number of converts gradually increased. The propagation of the new faith met with every species of opposition; but at length the contests became so frequent, while those who adopted Christianity greatly increased in number, that the national assembly, which met in the year 1000, took the matter into consideration. While the question for the establishment of the new religion was debated, a messenger hurried into the assembly, and announced that fire had burst from the earth in the southern part of the country, and was carrying destruction before it. The heathen party instantly exclaimed, that this was the vengeance of the gods against their presumption. But Snorro, who was a zealous advocate for the Christian cause, called out to them, "For what reason did your gods display their wrath, when the rock on which we stand was burning?" The place of assembly is in the midst of frightful proofs of the power of volcanic fire; and this exclamation of Snorro turned the scale in favour of the Christian faith. The decision of the assembly was solemnly pronounced by Thorgeir, the Laugman; and all religious disputes were immediately suspended. A church establishment was soon afterwards arranged, and the first bishop of Skalholt, Isleif, was ordained in the year 1057. From this period, during nearly two centuries, a pure religion was exercised by the Icelanders, undisturbed by the errors and superstitions of the Romish church.

Greenland and America discovered by Icelanders.

The discovery of Greenland, about the year 972, is another feature of this early age; and one still more remarkable was the discovery of the north-east coast of America in the year 1001 by Biorn Heriolfson, who was driven to the south while on a voyage to Greenland. A colony was established in Greenland, which subsisted till the beginning of the 15th century, when all traces of it were lost. About the same time, a material change for the worse appears to have occurred in the climate of Iceland, where, it is said, corn formerly grew. The loss of Greenland was occasioned by an unusual accumulation of ice, which has bound up the coasts ever since, and frustrated every attempt to reach the place where the once flourishing colony existed.

The part of America first seen was probably some part of the coast of Labrador. Leif, the son of Eric, the discoverer of Greenland, on hearing the report of this discovery, set out to pursue it; and passing by the coast first observed by Biorn, he came to a strait separating a large island from the mainland, probably that of Newfoundland. Thorvald, brother to Leif, went over to this new country, which, from finding wild vines growing in it, was called Vinland; after remaining two years, he was killed in a skirmish with the natives, who had not been seen till this time. A regular colony appears to have been afterwards established in Vinland. But after the early part of the 12th century, scarcely a vestige of this colony can be found, and the situation of Vinland is destined to perpetual obscurity.

Moral character at this period.

The moral character of the Icelanders, during this period of their history, seems to have kept pace with their intellectual endowments, and to have stood high. Previous, however, to the introduction of the Christian religion, some unnatural customs and superstitious usages obtained. The exposure of children, though not prohibited, was soon relinquished, after the morality inculcated by the New Testament came to be fully understood; and ceased more than a hundred years before the practice was abolished in Norway. The most singular superstition was the Beserkine. From the *Kristni Saga*, and the Ecclesiastical History of Iceland, we learn that the Beserkin were professed warriors, who, by means of magic, had rendered their bodies invulnerable. Rousing themselves by incantations into frenzy, these men committed every kind of violence, and rushed naked into battle. There is every probability that some of these were miserable and infatuated wretches, while others adopted the profession with the view of imposture.

Submision to Norway.

The independent and happy state of Iceland was not destined to be uninterrupted. The love of power produced intestine evils, which the ambition of Norway carefully fomented. The civil contests were not always trifling; for instances are recorded, in which fleets of twenty sail, and bodies of 1200 men, fought on one side. The desire of peace, and the promises of the Norwegians, now become jealous of the prosperity of Iceland, at length produced a formal proposal in the national council, that the country should be governed by a single potentate; and in the year 1261, the whole, except the eastern province, submitted to Haco, king of Norway. A few years afterwards, the submission of Iceland was completed, but under conditions which still maintained their rights and their commerce. In 1280, Magnus, the successor of Haco, gave to the island the code of laws well known by the title *Jonsbok*, which was no more than a revised copy of the ancient laws.

Transference to Denmark.

The last political change which occurs in the history of Iceland, was its transference with Norway to the crown of Denmark in the year 1380. A period of tranquillity, during which rank and property became more equalized, and trade was almost wholly transferred to other nations, succeeded; and a feeling of dependence checked enterprise, while vigour and activity were gradually lost. In the year 1482, a pestilence carried off nearly two-thirds of the population; and another broke out towards the close of the century. In addition to these calamities, the Icelanders were at this period exposed to the incursions of pirates,

Calamities at this period.

who plundered their property, committing frequent murders, and carrying off the inhabitants. "These events," says Dr Holland, "which concurred with the causes before described, in depressing the spirit of the people, and destroying the strength and prosperity of the country, are recorded in the annals of Iceland with an affecting and almost painful simplicity. No attempts are made to excite a sentiment of commiseration, beyond what humanity would of itself yield to the recital of such complicated evils. We are told that whole families were extinguished, and districts depopulated, by the virulence of the disease; that the learned, the pious, the wealthy, and the powerful, all dropt into a common grave; that the labours of industry ceased; that genius and literature disappeared; and that the wretched remnant of the Icelanders, scarcely themselves saved from destruction, sunk into a state of apathy, superstition, and ignorance. In pursuing his melancholy narrative, the historian sometimes looks back to the former celebrity and splendour of his country; but he goes no farther; and all beyond is left to the feelings and imagination of the reader."

The Introduction of Popery.

But the decline of literature, and of the national character of the Icelanders, may be traced to more remote causes. Europe began to emerge from darkness and barbarity, and the continental nations gradually rose into equality in learning. The poets and historians of Iceland were therefore received with less distinction. The errors, superstitions, and tyranny of the church of Rome, broke in upon the pure and peaceful worship of Iceland about the end of the 12th century. The levying of Peter's pence, and raising money by indulgences, were not warded off by the poverty of the people, who were oppressed even by the native bishops. From the 13th to the 16th century, the annals of Iceland present nothing of interest; being filled with records only of the depression of all mental exertion, and of physical calamities.

Of the reformed religion.

The reformation of religion, and the introduction of printing, by the establishment of a press at Hoolum about the year 1530, seemed to be the dawn of renewed life to Iceland.

The reformation was not effected without violence. John Areson, bishop of Hoolum, was the most strenuous and violent opposer of the introduction of the Lutheran doctrines. He assembled a body of armed men, and marching southward, attacked and seized Einarson, bishop of Skalholt. He was arrested himself, however, the following year, by the order of Christian III. in whose continental dominions the reformed religion had been adopted. Areson, and his two natural sons, were beheaded at Skalholt; and in 1551 the new doctrines were legally established and universally received. The schools were re-established; but so great had been the depression of learning, that it was found difficult at first to procure men of sufficient knowledge to superintend them.

Now that science began to illuminate the rest of Europe, we cannot expect to find the former condition of Iceland restored, nor even the progress of knowledge keeping pace with that of other countries. The physical evils to which Iceland is exposed operated with greater effect than before; and though we can enumerate several eminent individuals whose writings are creditable and useful, yet their literary fame has seldom stepped beyond their native island.

To the zeal of Thorlakson, bishop of Hoolum, who ushered many useful works into the world from the Icelandic press superintended by himself, the people were indebted for the first translation of the Bible into their own language. It first appeared in 1584. The friend of Thorlakson, Arngrim Jonas, published twenty-six different works in divinity, history, jurisprudence, and philology, all of which exhibited very extensive acquirements. Another eminent historical writer was Biorn de Skardsaa, who published Annals of Iceland from the year 1400 to 1645, and several other works.

Attacks of foreigners.

The 17th century is destitute of any important events. At its commencement piratical incursions of the French, English, and Algerines, were not unfrequent. Of the latter, a large body landed on various parts of the southern coast, and on the Westman islands; and besides plundering their effects, murdered nearly fifty of the inhabitants, and carried 400 of both sexes into captivity. This happened in the year 1627; and nine years afterwards, when the king of Denmark had paid a ransom, only thirty-seven survivors were found. This century also disgraces Iceland by the superstitious enormities which were practised. A belief in necromancy was so prevalent, and held in such horror, that, within the period of sixty years, twenty persons perished in the flames.

Ravages of the small-pox.

The commencement of the 18th century was marked by the destruction of 16,000 persons by the small-pox. From 1753 to 1759, the seasons were so inclement, that famine carried off 10,000 people, besides vast numbers of cattle. In 1783, the most terrible volcanic eruption on record broke out from the neighbourhood of the mountain of Skaptaa, and for more than a year showered ashes on the island, and enveloped it in a thick cloud of smoke. Cattle, sheep, and horses were destroyed, and a famine ensued. The small pox again appeared; and in a few years above 11,000 people perished.

Modern authors.

Notwithstanding the calamities incident to their situation, the Icelanders have still preserved literature from decline. In later times we have the names of Torfæus, Arnas Magnæus, and Finnur Jonson, who have greatly adorned the modern literature of their country. Arnas Magnæus was the son of an obscure priest, and by his talents he raised himself in 1694, when only thirty-one years of age, to the situation of professor of philosophy in the university of Copenhagen; and soon afterwards he was appointed professor of northern antiquities. He made a splendid collection of books and manuscripts in the Icelandic language, which was almost entirely destroyed by fire in 1728. His pupil and friend Finnur Jonson has eminently contributed to preserve the literary character of his country. He was made bishop of Skalholt in 1754, and devoted a long life to the improvement and happiness of his countrymen. His Ecclesiastical History of Iceland is an admirable work, though somewhat minute in its details; and presents a degree of patient and accurate research which has seldom been equalled. The well known exertions of Professor Thorkelin, in behalf of Iceland, are happily yet continued; but the state of war in which Europe has so long been immersed, has brought Iceland into a state of suffering from which she cannot soon be relieved.

In the present times, individuals are not wanting, who exhibit, though less successfully, all the zeal of their ancestors in the pursuit of learning. Their acquirements are such as would grace any society; and when the remoteness of their situation and the multitude of their privations are considered, the picture which Iceland presents at the commencement of the 19th century, is truly worthy of admiration. The school is not now so flourishing as it used to be; but education is systematically carried on amongst all ranks;

and the degree of information possessed by the lower orders is far from being inconsiderable.

Schools.

Two schools were founded in the 16th century, one at Hoolum, in the northern quarter of the island, and the other at Skalholt. These were united and transferred to Reikiavik, towards the end of last century; and a few years ago, it was moved to Bessestadt, the former seat of the governors of Iceland. The arrangements for conducting this school have met with a severe interruption in the war between England and Denmark, and every thing has the appearance of disrepair and approaching ruin. The establishment consists of three masters and twenty-four scholars; the funds not admitting a greater number. The head master, who has the title of Lector Theologiæ, has a salary of 600 rixdollars. He superintends all the concerns of the school; the study of theology being his particular department. One of the most accomplished men in Iceland, Steingrim Jonson, was lately removed from this situation to one of the most valuable livings in the country, that of Oddè. This, it was understood, was preparatory to his becoming Bishop of Iceland, on the demise of the present bishop. His successor in the school is of the same name, and is reputed a man of great learning and talent. The second master teaches Latin, history, geography, and arithmetic; and the third, the Greek, Danish, and Icelandic languages. The bishop examines the scholars once a-year, according to a prescribed form of proceeding. After studying at this school, some of the young men go to finish their studies at Copenhagen; but by far the greatest number return to their homes, where, secluded from the society even of their own countrymen, and while the darkness of a long winter gives them leisure, they often pursue their studies, and acquire no inconsiderable extent of knowledge.

Poetry.

Societies.

Poetry is still cultivated with surprising eagerness; and the number of manuscripts of unpublished works is very great. History is not so much cultivated; and science, strictly so called, scarcely at all. In the year 1779, a society was instituted at Copenhagen for aiding the literature of Iceland, and bettering the condition of its inhabitants. This society, which comprehended among its members, not only eminent Icelanders and Danes, but many foreigners of note, published fourteen volumes of transactions, containing essays on history, poetry, agriculture, the fisheries, and the natural history of Iceland. In 1790, a project was made for transferring the society to Iceland, which occasioned such dissensions as suspended all the proceedings, and the name only of the society now exists.

A second Icelandic society was established in the island in the year 1794, by the present chief justice Stephenson, whose exertions in behalf of the literature and general improvement of his country have been indefatigable. The number of members in this society was originally 1200, and each contributed a dollar annually. The printing establishments at Hoolum and Hrapsey having fallen into decline, were purchased by the new society, and an establishment erected at Leira. From thence have issued a considerable number of works printed for the use of the society. Various occurrences, among which the war between Denmark and Great Britain had the chief influence, have occasioned the almost total extinction of this society. It is to be wished that, as war has ceased to disturb the nations of Europe, the Icelanders will be enabled again to enjoy the only recreation which their situation admits; and that their history, political and literary, of which we have given an outline, will not cease to be interesting. A new society was established in 1816, by the exertions of a very able young man, Mr Raske, under librarian in the royal library at Copenhagen; and there can be no doubt of Icelandic literature reviving under his care in disseminating, with the assistance of this Society, the means by which the Icelanders may overtake learning in the rapid progress she has made.

Government, laws, religious establishments.

The circumstances of Iceland have required little or no alteration either in the laws, or in the form of government which was established 600 years ago. The supreme authority is entrusted to an officer, with the title of Stiftamtmand, who has a general superintendence of every department. Under the Stiftamtmand, each of the four provinces into which the island is divided, is governed by an Amtmand, or Bailiff, whose duties are the same as those of their superior within their respective jurisdictions. Each province is divided into syssels or shires, over which the sysselmen preside. These officers collect the taxes, and are paid by a rate out of the amount collected. They hold courts of law; and on the whole their duty is in almost every respect the same as that of sheriffs in Scotland.

In each parish there is an officer called Hreppstiore, whose chief business is to attend to the concerns of the poor, and to assist the sysselman in the preservation of the public peace. For the decision of petty disputes among the people, there are a certain number of persons in each parish, denominated Forlikunarmen, who may be called official arbiters.

All cases, whether civil or criminal, are first brought before the sysselman, who holds a court once a-year, or oftener if necessary. In criminal cases, and in public suits, the amptmand orders the trial, after previous examinations, on behalf of the crown. From the inferior court there is an appeal to the high court of justice, which sits six times in the year at Reikiavik. This court was established in the year 1800, at which time the assemblies at Thiugvalla were abolished. The Stiftamtmand presides, but has no voice in the proceedings. There are three judges, the first is called Justitiarius, and the other two Assessors. Evidence and pleadings being heard, the causes are determined by a majority of the three judges. From this court there is an appeal to the superior courts at Copenhagen.

Punishments.

The punishment of petty offences is fine and whipping. Sheep-stealing, which is the most common offence, is punished by imprisonment and labour, for a term of three or five years, according to circumstances. A repetition of crimes brings on the offender transportation to Denmark, where he is confined at hard labour in the work-house, for the remainder of his life. The infliction of such severe punishment is, however, very seldom required. Murder is exceedingly rare; and except in cases which subject the criminal to capital punishment, he is not confined before the time of trial.

Property.

With regard to property, no entail of land is allowed. When a proprietor dies, his lands are valued and divided into shares, of which the eldest son has the choice. The daughters receive an equivalent to half the portion of a son. A wife surviving her husband, possesses half of his estate. The rights of tenants are such as would essentially contribute to the improvement of the soil, were sufficient inducements held out to encourage it. A tenant cannot be removed, unless the proprietor can bring proof that the farm has been neglected, or that the farmer has not behaved well. Leases are not common; but letting land from year to year is a frequent practice, six months notice to quit being necessary. Although a tenant cannot be removed while he conducts himself well, and manages his land properly, he may quit his farm whenever he pleases. On every farm there is a permanent stock of cattle and sheep, which is transferred from tenant to tenant, and for which a certain fixed rent is paid. As many more cattle and sheep as the farm can maintain may be kept. Besides the rent for the stock, a land rent, landskuld, is paid according to an old valuation.

Taxes. The public taxes are so inconsiderable, that they are not sufficient to defray the expences of the civil establishment. Some of the taxes are levied on property, regulated by an annual survey made by the Hrepstiores. In ancient times, the calculation was made according to the number of ells of the cloth called *wadmal*, which each person possessed or could manufacture in a year, and the tax was levied on every hundred ells. The term hundred is now applied differently, and an Icelander is said to possess a hundred when he has two horses, a cow, a certain number of sheep, a boat and fishing materials, and forty dollars in specie. When a person possesses more than five hundreds, he pays, over and above the stated tax, twelve dried fish. This tribute is called *tuind*,* and increases in proportion to the amount of property, and is allotted equally to the public revenue, the church, and the poor. There are several other taxes of small amount. The produce of the taxes being chiefly in kind, is collected by the sysselmen, and by them paid over to the landfoged, or public treasurer, who disposes of them to the merchants. The sysselmen are paid according to what they collect; and even when they are very successful, their trouble is but ill rewarded. The landfoged is subject to the chance of gain or loss in his transactions with the merchants; and he retains a third part of the whole as his salary.

The taxes for the maintenance of the poor are much more severe on the people than those levied for the public. There is no regular establishment for the poor, if we except three small buildings in different parts of the country allotted for the reception of incurable lepers. Every farmer or householder is by law obliged to receive and support his own destitute relations; and should he have none such, orphans, and those whose age and infirmities render them incapable of supporting themselves. The expence thus incurred amounts sometimes to twenty or thirty times the amount of his public taxes, when a householder does not choose to receive paupers into his family.

The religious establishment of the country consists of a bishop, provost, and parish priests. The two sees of Skalholt and Hoolum happening to become vacant at the same time, they were united in the year 1797, in the person of Geir Vidalin, who now enjoys the title of Bishop of Iceland, and is settled at Reikiavik. The island is divided into 184 parishes, in most of which there is more than one church, on account of the scattered state of the population, the average of which for each parish may be about 260. There are nineteen provosts, each of whom, besides the general superintendance of his district, has the charge of a parish.

Ecclesiastical revenue. The revenue of the bishop amounts to 1800 dollars; that of the parishes is very unequal, some being in value nearly equal to 200 dollars, on account of the goodness of the farms attached to the livings, while others, with a greater population, are scarcely worth thirty dollars. The glebes add considerably, however, to their scanty allowances; and as every farmer is obliged to furnish the priest with a day's work, and to keep a lamb for him, his farm costs him but little labour. He also receives occasional small offerings, and perquisites for officiating at marriages, baptisms, and burials. The churches are in general neat but plain buildings, constructed of wood and turf. Some of them indeed are little better than hovels, while others are large and comfortable. At Reikiavik, there is a large church built of lava, and roofed with tiles. A more elegant one of this kind is to be seen at Bessestad. The church in the Westmann islands is reckoned the most elegant.

Young men destined for the church, after they have left the school, and been admitted as probationers, earn their livelihood by fishing and other labour, and after a certain term are examined, and received into orders, after which they await a settlement, the prospect of which is often very distant, and when obtained does not yield ease and comfort. The habitations of the priests are seldom better than those of the farmers, and are not better furnished; a bed, a table, and a few chairs, and those very indifferent, being the whole stock, in addition to a few boxes and chests, in which the clothes and chattels of the family are kept. Here, however, learning and genius are to be found; and an attention to the duties of their station is displayed by the Icelandic priests, which may well excite feelings of shame among those of other countries, who have no privations to hinder them from the proper performance of their duty. The following description of a Sabbath scene in Iceland, is not more elegant and affecting than it is correct. It is from the pen of Dr Holland, and we quote it from Sir George Mackenzie's Travels. **Sabbath scene.** "The Sabbath scene at an Icelandic church is indeed one of the most singular and interesting kind. The little edifice, constructed of wood and turf, is situated, perhaps, amid the rugged ruins of a stream of lava, or beneath mountains which are covered with never-melting snows; in a spot where the mind almost sinks under the silence and desolation of surrounding nature. Here the Icelanders assemble to perform the duties of their religion. A group of male and female peasants may be seen gathered about the church, waiting the arrival of their pastor; and all habited in their best attire, after the manner of the country; their children with them; and the horses which brought them from their respective homes grazing quietly around the little assembly. The arrival of a new comer is welcomed by every one with a kiss of salutation; and the pleasures of social intercourse, so rarely enjoyed by the Icelanders, are happily connected with the occasion which summons them to the discharge of their religious duties. The priest makes his appearance among them as a friend; he salutes individually each member of his flock, and stoops down to give his almost parental kiss to the little ones, who are to grow up under his pastoral charge. These offices of kindness performed, they all go together into the house of prayer."

Commerce. The trade of Iceland has never been managed in such a way as to be of important benefit to the natives, of whom but a small number are engaged in it. The following Tables, taken from Stephenson's *History of Iceland during the 18th Century*, will serve to give a correct idea of the state of commerce.

---

* Whence, perhaps, is derived our Scottish term *Teinds*.

A volume was published, in the year 1787, at Copenhagen, by Royal authority, entitled *Regulations for the Trade and Navigation of Iceland.* This was at the time when the trade was declared free; and the volume contains Tables of the Exports of Iceland from 1764 to 1784; but we have not had an opportunity of copying them.

* Eskefiord is situate on the same bay as Rodefiord.

Iceland.

Weights and measures.

WEIGHTS AND MEASURES USED IN THE ISLAND.

Liquid Measure.

1 pipe contains	3 ame	or	120 gallons.
1 oxhoved (hogshead)			60
1 ame	4 ankers	or	40
1 tonde	3 ankers	or	30
1 anker	5 kutting	or	10
1 kutting	4 kander	or	2
1 kande	2 potter	or	0½
1 pot	4 pæle	or	2 pints.
1 pæle		or	0½ pint.

Corn Measure.

1 tonde (barrel) = 8 skepper, or 4 English bushels.
1 skepper (½ bushel) contains 18 potter or quarts.

Cloth Measure.

1 alen or yard = 25 English inches, or two-thirds of a yard, and is divided into quarters.

Weights.

1 skippund = 20 lisepund, or 3 cwt. 22 lb. English.
1 lisepund = 16 pund, or 17 lb.
1 pund = 16 onzer, or 1 lb.

The Danish pound is 12 per cent. heavier than the English.

Farm houses.

We have already mentioned the laws respecting property, and the conditions in which a tenant holds a farm. A farm house in Iceland has the appearance of a small village; the dwelling house, all the out-houses, and the hay yard, being within a general inclosure of turf, four or five feet high, and seldom less than five or six feet thick. The doors to the different apartments are generally arranged on the south side, and each has a sort of pediment above it, surmounted by a vane. The access to the dwelling house is by a long narrow passage, into which the different rooms open. Each room is separated from the next by a thick partition of turf, and has also a separate roof, through which the light is admitted by bits of glass or skin. The principal rooms of the better sort of people have small glazed windows in front. Ventilation is not attended to, warmth being the chief object in the construction of the houses; and the consequence is, that the smell is to a stranger almost insupportable. The houses are generally built on a rising ground, and in the middle, or as near as possible to the land devoted to the hay crop. On this land, which is in general much broken into little knolls or hillocks, the manure is spread in the month of May; and about the end of July the grass is cut, when it is scarcely more than six inches long. In this operation a very short scythe is used, and the Icelanders cut with it very neatly and expeditiously. The hay is kept chiefly for the cows, though in very severe weather the sheep and horses get a small share. As soon as the crop near the house is secured, the farmer gives a feast; and when the whole is safe in the hay yard, a fat sheep is killed, and another feast takes place.

Farm-houses.

Cows.

The cows are very like the Scotch Highland sort, known in England by the name of Kyloes. No attention is paid to breeding stock; and in general we find the best stock on farms where the winter food is in greatest plenty. During the summer there is great abundance of pasturage.

Sheep.

The sheep appear to be a mixed breed, carrying long and coarse wool. The wool is removed by pulling it when it appears loose. A great quantity of mutton is salted for exportation in the northern districts.

Cheese and butter.

Very little cheese is made, butter being the chief object in the dairy. It is barrelled without salt, and is thus kept several years. The older it is the more it is prized. In this state it reaches a certain stage of rancidity, beyond which it does not pass; and it is wonderful how long it keeps.

Horses.

The horses are of a small breed, but stout, and very hardy. Those used for riding are trained to what is called pacing; and, where the ground is tolerably smooth, they go very swiftly, the motion being very easy and pleasant to the rider. The statistical information contained in the following Tables, was partly furnished to the writer of this article by Bishop Vidalin, and is partly taken from Stephenson's *Iceland in the 18th Century.*

TABLE *of the Population of Iceland in the Year* 1801.

Total . . .	4761	7401	5821	735	590	231	45	21476	25731	47207

This Table, exhibiting the state of the population of Iceland in the year 1801, is taken from the register of the Bishop, to whom returns are regularly made by the priests. The original Table contains also a detailed statement of the ages of the whole population of the island, of which the following is the general result:

	Males.	*Females.*
Under 10 years of age	6231	6300
From 11 to 20	3207	3299
21 . 30	3385	4060
31 . 40	3190	3901
41 . 50	1838	2460
51 . 60	1707	2453
61 . 70	1162	1842
71 . 80	592	1096
81 . 90	158	285
91 100	6	35
Total	21476	25731

The Bishop not having made up Tables from the most recent returns, could only furnish us with the general results of the years 1804 and 1808. He said that the population was on the increase.

It appears that the excess of the female population of the island is very considerable; and that the average longevity of the women is greater than that of the men. The population has varied little during the last 100 years.

In the year 1703 it amounted to	50,444
1770	46,201
1783	47,287
1801	47,207
1804	46,349
1808	48,063

The population of Reikiavik in the year 1806 (including 27 prisoners in the Toght-Huus) was 446. Of this number 134 were working men. Belonging to the town there were 35 cows, 2 sheep, 92 horses, 3 large boats, 26 of a middle size, 9 small ones, and 17 gardens.

---

[*] In the year 1707, the small-pox destroyed 16,000 people. Between 1753 and 1759, famine carried off 10,000, and vast numbers of cattle perished.

[†] In the year 1783, the great eruption from Skaptaa Jokul destroyed a great number of cattle; but the loss in this Table appears to be exaggerated.

Manners and customs.

The manners of the Icelanders are exceedingly simple, and respectful as well to each other as to strangers. The women, however, appear to be rather restrained, it being customary for them to wait at table, and do every little office usually committed to servants in our own country. There are but few peculiar customs, and those not of particular interest. The depressed state in which the Icelanders are kept by the wretched policy of Denmark, effectually subjugates those dispositions which, in countries where freedom teaches men to be independent, quickly display themselves in innocent and recreating amusements. The sole occupation of the Icelander is to provide food for the winter season; and when the rigour of an arctic winter confines him to his hut, and the sun scarcely sends a ray to illuminate the dreary scene around, he amuses himself with the tales of elder times, when his country stood high, and her learned men and warriors were honoured in every European court. That our lamentations are vain, that the Icelanders are condemned to misery yet greater than that they now endure, we fear is too true.

Topography.

A country less inviting to the enterprize of adventurers than Iceland can scarcely be imagined. The mountains covered with eternal snow, the plains devastated by volcanic fire, seem to present no attractions. The country in general is mountainous; but in some districts, particularly those extending from the south to the north coasts, nearly through the centre of the island, there are extensive plains, for the most part dreary wildernesses, and covered with herbage only near the sea, or where morasses have formed. The highest mountains are on the east and west sides of the island. They are in groups, seldom in chains; and those called *Jokuls*, which are covered with perpetual snow, are chiefly, if not all, volcanic. The coast, except towards the south, is much indented by arms of the sea; but with the exception of Havnefiord, on the south-west, there is scarcely a safe winter harbour.

Rivers and lakes.

There is a considerable number of lakes in different parts of the island, some of which are of great extent. The principal are those called Thingvalla Vatn, My Vatn, and Fiske Vatn. The first of these is about ten miles long, and from three to four broad. There are many large rivers in Iceland, formed by the melting of the snow on the Jokuls; and these have all a turbid appearance; some of them being so white as to resemble milk diluted with water, have received the name Huit-aa, or the White River. Several emit a fetid smell, particularly when they issue from the snow. Besides these large rivers, there are many smaller, the water of which is transparent. They rise from the lower grounds. Along almost the whole southern coast eastward from Eyarback, where the great river Elvas empties itself into the sea, there are extensive shoals, formed, no doubt, by the depositions of the rivers proceeding from the great range of Jokuls to the eastward of Mount Hekla.

The population is chiefly established near the most convenient harbours, and where fish abound. Reikiavik is the principal place, and the seat of government. It has been chosen for the convenience of the harbour, and of the gravel beach, a thing of rare occurrence in Iceland. The country around is as bleak as can well be imagined.

Volcanoes.

It is impossible to travel many miles in Iceland without meeting the frightful effects of subterraneous fire. This miserable country has been exempted from the calamities of an eruption since the year 1783, at which time the most dreadful, ever recorded, took place. On the first of June of that year, the southern districts were shaken by violent earthquakes. These continued, and were most alarming on the 8th, when smoke was seen rising among the mountains called Skapta Jokul. There appeared several eruptions from different spots, at considerable distances from each other. The showers of ashes and stones, the terrible noises, and the darkness in which the country was involved, foreboded an awful calamity. The large river Skaptaa was dried up, and the channels filled with liquid fire. Habitations were devoured, and the green pastures buried; and the wretched inhabitants had the dismal prospect of being overwhelmed by the lava, or of perishing by famine. The lava was for a time retarded by its flowing into a lake; but its progress was not stopped, when a fresh eruption took place on the 18th of June. The lava having divided, and begun to move in various directions, the scene became more and more dreadful. On the 22d fresh eruptions broke out, and continued multiplying till the 13th of July. On the 20th, the lava towards the western side of the district of Skaptaa-fell ceased to flow. To the eastward, on the 3d of August, smoke was seen to rise from the mountains towards the north; the waters of the great river Hversfliote were dried up; and on the 9th of August the lava approached by the channel of the river, overflowing in one evening an extent of four miles. This eruption continued longer than the first; and it is said that a fresh one happened in February 1784.

Mount Hekla.

Mount Hekla has been quiet for half a century. The volcanic fire appears to have been most active in the south-east and north-east districts, during the last century. Previous to the eruption of 1783, flames were seen rising from the sea, about 30 miles off Cape Reikianes, and several small islands appeared which afterwards sunk, leaving however a sunken reef, which renders the navigation round the Cape dangerous in thick weather. Similar phenomena have appeared in other parts of the world; the most recent being the eruption off St Michael's, one of the Azores, which produced the island which was called Sabrina.

Hot springs.

The greatest curiosities which Iceland presents, are the springs of hot water, many of which are justly considered as among the greatest wonders of the world. They are, we believe, greatly more abundant in this than in any other volcanic country; but the interest which the number and variety of these hot springs excites in a person who never saw any thing similar, is quickly lost in the feelings which are roused on beholding the magnificent and tremendous explosions of the Geysers. These extraordinary fountains are situate about sixteen miles north of Skalholt, on the east side of a small ridge, separated from some high mountains by a narrow swamp. Besides the principal fountains, there are a great number of boiling springs, cavities full of hot water, and several from which steam issues. There are also some places full of boiling mud, grey and red.

Great Geyser.

The silicious depositions of the water of the Great Geyser, have formed for it a bason 56 feet in diameter in one direction, and 46 in the other; a projection from one side, causing the circumference to deviate from the perfect circle. In the centre of this bason is a cylindrical pipe or pit, ten feet in diameter. Through this pit the hot water rises, gradually filling it and the bason, after which it runs over in small quantities. At intervals of some hours, when the bason is full, explosions are heard from below, like the firing of cannon at a distance; and at the same time, a tremulous motion of the ground is felt around the bason. Immediately the water rises in a mass from the pit, and sinking again, causes the water in the bason to be agitated and to overflow. Another and stronger propulsion follows, and clouds of vapour ascend; at length strong explosions take place, and large quantities of steam escaping, the water is thrown to a great height, generally from 30 to 90 feet. The steam coming in contact with the air is condensed into vapour, thick clouds of which are tossed and rolled one over another with great rapidity, the whole forming a very singular and magnificent exhibition. After continuing for some time, the explosions cease, when the bason and pipe are found empty. Bursts of steam sometimes take place when the water is rising, without any warning by subterraneous noise. These phenomena are caused evidently by the production and confinement of steam in cavities, so formed, that when the accumulation arrives at a certain point, the pressure of the water opposing its escape, is overcome, and the water is thrown out before it.

New Geyser.

The New Geyser, as it was called by Sir John Stanley, is about 130 paces from the great one. It is an irregularly shaped pit, nine feet in its greatest diameter. About 20 feet below the orifice, which is not surrounded by an accumulation of silicious matter as the other, the water is seen in great agitation. At irregular intervals, the water is tossed out of the pit to a great height, followed by a prodigious rush of steam, accompanied by a roaring noise. The force is so great that, even when there is a good deal of wind, the vapour forms a perpendicular column nearly 70 or 80 feet high; and when large stones are thrown into the pit, they are shivered to pieces, and thrown out to a height often far beyond that of the jet of vapour and water.

At the time Mr Hooker saw it, there was a greater quantity of water than when either Sir John Stanley, or Sir George Mackenzie witnessed its eruptions. Indeed, what Mr Hooker has described as a column of water, Sir George Mackenzie describes as one of vapour. When we consider the immense power of the agent which sets these grand waterworks in play, it is by no means difficult to suppose frequent alterations in their movement and appearance. The destruction of a natural valve, or a slight change in the configuration of the subterraneous pipes and cavities, might occasion variations in the phenomena from time to time.

Singular spring called Tunguhver.

The most curious of all the springs in Iceland is the *Tunguhver*, in the valley of Reikholt. Among a great number of boiling springs, are two cavities within a yard of each other, from which the water spouts alternately. While from one the water is thrown about ten feet high in a narrow jet, the other cavity is full of water boiling violently. This jet continues about four minutes, and then subsides, when the water from the other immediately rises in a thicker column to the height of three or four feet. This continues about three minutes, when it sinks, and the other rises, and so on alternately. It is difficult to imagine the structure of the cavities which occasion this irregular alternation; nor would it be easy to construct a piece of mechanism, of which steam is the prime mover, to imitate the phenomena.

In the middle of the river, which runs through the valley of Reikholt, is a small rock, from the top of which hot springs issue. At Reikholt is a bath, which was constructed 600 years ago by the famous Snorro Sturleson. It is fourteen feet in diameter, and six feet deep, being supplied with hot water from a spring about a hundred yards distant, by means of a covered conduit, which has been much damaged by an earthquake. There was also a spring of cold water brought to it, so that any desired temperature might be obtained.

On the sulphur mountains, in the district of Guldbringè, are a number of jets of steam, and natural cauldrons of black boiling mud; and there is scarcely a district in the whole island without such indications of subterraneous heat, which must occasion the most singular contrast with the winter snows and ice, through which, at that season, they rise.

At Reykum in the south, and near Husavik in the north, are hot springs, which come next to the Geysers in magnificence.

Natural history.

Quadrupeds.

The zoology of Iceland presents nothing remarkable. Of indigenous quadrupeds the number is very small, and must be limited to the fox, of which there are two varieties, the Canis lagopus, and Fuliginosus. The rein-deer, the rat, and the mouse, have all been imported; as well as the domestic animals the dog, the cat, the goat, the sheep, the ox, and the horse. Polar bears are occasional visitors, coming from the ice, which takes ground on the north and east coasts during winter. As soon as they appear, they are pursued and destroyed. The skins of the foxes, particularly those of the *Canis fuliginosus*, or blue fox, is a valuable article of commerce. The rein-deer are wild, and are derived from an original stock of three, which were all that survived of some that were sent from Norway in 1770. Instead of being serviceable, they often destroy the grass which is preserved for hay.

Fishes.

Several species of seals frequent the shores in considerable numbers; but they are not much sought after.

Whales are seldom seen on the coasts of Iceland; but that variety of Delphinus, which we mentioned in the article Faroe, named in Orkney the ca'ing whale, appears frequently in large shoals. The shark is common on the coasts, and is taken by large hooks fastened to an anchor by chains and strong lines. Of the skins, shoes are made; and they are valuable to the inhabitants of some districts for the oil which they afford, and also for their flesh.

Birds.

The cinereous eagle, or erne, is very common. The Iceland falcon, formerly so much prized, is now seldom seen, though it has not for many years been molested.

Ravens are found in great numbers near every habitation on the coast, watching for the offal of fish. They breed in the cliffs at a considerable distance from the shores.

The snow-flake, wheatear, white wagtail, golden plover, snipe, and whimbrel, together with the ptarmigan, are the other principal land birds of Iceland.

Eider ducks.

Every kind of water fowl common to northern latitudes is found on the coasts of Iceland, and on the lakes. Swans frequent the lakes and swamps in great numbers. But of all the varieties which breed in the country, the eider duck is, from its habits and usefulness, the most remarkable and valuable. Early in June, these birds collect in great numbers at every place adapted for making their nests, and where their food is in plenty. The nests are formed on the ground, generally in hollows among the grass, of straws mixed with the down which they pluck from their breasts. There is always a quantity of down round the nest, sufficient for covering the eggs when the ducks go to feed, which they do regularly during the time of low water, when they can get at the shell-fish among the seaweeds. At this time these birds lose all their wildness, and suffer the enemy, avoided by all the lower creation, man, to approach, and even to touch them, and to lift them from their nests. The drakes are not so fearless; but they frequently remain near the nests, and express their displeasure when any one touches them. As soon as the young ones have left the shells, and get to the water, the eider ducks become as wild as any other bird, and in a month or six weeks almost all of them disappear, and it is not known to what place they resort. The nests are robbed of a certain number of eggs, and of the down. The former are a great luxury to the natives, and the latter is a valuable article of export. It is part of the employment of the women during winter, to pick the straws and refuse from the down.

Fishery. It is from the sea, however, which the Icelanders derive their chief subsistence and profit. The cod is very plentiful on the coasts; and formerly the fishery of Iceland was prosecuted by the English and French with great success. The fishery commences early in February; and the inhabitants of the interior move at that time towards the different fishing stations, and travel in darkness through the snow. They engage with the owner of a boat to obey every call for fishing, and to assist in the general labour, and he receives a share of the fish in return for the use of the boat. When a sufficient quantity has been taken, the people from the country return home, leaving the care of drying the fish to the inhabitants of the fishing villages. In June, the farmers carry to the trading stations all their marketable commodities, to be exchanged for necessaries and a few luxuries, and on their return they carry home their fish to serve them during the next winter. The haddock is also taken in great plenty, and grows here to a very large size. The cod is chiefly cured for exportation, and the haddock for home consumption. The ling, skate, hollibut, flounders, and the cat-fish, are common, and are likewise dried for winter use. The skate is the least esteemed of all the other fish, and is seldom if ever eaten fresh. Herrings are taken on the north coast; but though vast shoals of them frequent the bays, this branch of the fishery is not much attended to. Sharks are an important object on the north-west coast, and a considerable quantity of oil prepared from them is exported.

Those travellers who have visited Iceland, having been there only during a short summer, and their time having been almost entirely occupied with viewing the country and its more prominent curiosities, have not pursued zoological enquiries very far. From what Mr Hooker says, the insect tribes seem to offer something new. That gentleman has furnished us with a very complete botanical catalogue, to which we refer such of our readers as desire particular information regarding the vegetable productions of this remote island. The birch is the only tree which withstands the rigours of an arctic winter; but its growth is limited, in the most favourable situations, to five or six feet.

Mineralogy. The greatest portion of Iceland is mountainous; the highest elevations appearing on the east and west sides, while extensive plains appear, with little interruption, to extend from north to south across the island. The highest mountain the height of which has been ascertained, is said to be about 5500 feet. The Sneefell Jokul, which bounds the western extremity, and has been esteemed by the natives the highest in the island, was measured trigonometrically by Sir George Mackenzie, and ascertained to be 4558 feet above an extensive beach formed near Stappen. It is probable that none of the Jokuls exceed 6000 feet. Many of them are very extensive, forming long ridges; a shape which, were it not for their characteristic covering of perpetual snow, would tend to lessen their apparent elevation to the eye. The height of the curve of congelation may be taken for Iceland, at 2829 feet, as a mean; and thus a tolerable idea of the heights of the mountains may be had, when an opportunity occurs of observing the snow line on the Jokuls. From what has been actually observed, and from the best information, it appears that all the Jokuls are of volcanic formation; in other words, that they are either active or extinct volcanoes. The greatest height of the other mountains which are not volcanic, does not much exceed 2000 feet. They are all of the trap formation; and this does not appear to reach a great height in the northern hemisphere. In Faroe, its greatest elevation appears to be somewhat above 3000 feet. As far as has yet been discovered, the formations in Iceland are limited to the flœtz trap, volcanic, and alluvial, and those of Faroe to the first and last. The flœtz trap of Greenland, that of Iceland, and of Faroe, are probably connected; and the two last may be supposed to rest on primitive rocks, as the Greenland formation has been ascertained to do.

The beds of trap are inclined for the most part at a small angle to the horizon, dipping to the eastward of the meridian; and in this respect they agree with those of Faroe.

The beds consist chiefly of amygdaloid, containing zeolite, chalcedony, opal, quartz, arragonite, and calcareous spar. The base of the amygdaloid is for the most part wacke. There are many varieties of greenstone, from the most compact to that whose component parts are of large size; felspar and augit occurring in crystalline masses of from a quarter to half an inch. Greenstone occurs also in veins, and it is in this form only that basalt has been observed in Iceland and Faroe. The veins of Iceland, and some of those in Faroe, were found to have their sides vitreous, somewhat resembling black pitchstone, and gradually passing into the character assumed by the mass of the veins. Greenstone occurs columnar. In the island of Vidöe, there are columns formed of tables several inches in thickness, and from three to five feet in diameter; and in some instances, from decomposition, easily separable from each other. Some of the tabular columns have the appearance of the tables being composed of oval concretions, rendered visible by decomposition.

Beds of tuf of large dimensions are frequent; and if they are to be denominated from the formation in which they occur, they may be called trap tuf. The resemblance which they bear to volcanic tuf is, however, in many cases remarkably strong. They occur most frequently among a class of rocks, which have been distinguished by Sir George Mackenzie by the name submarine lavas; and we shall now quote from that gentleman's account of Iceland, the description of these rocks. He has selected a particular mountain which presented a precipitous face about 2000 feet high, and which, but not without considerable difficulty and hazard, he and his fellow-travellers ascended, taking specimens from each bed, a series of which is preserved in the cabinet of the Royal Society of Edinburgh. "The mountain of Akkrefell stands perfectly detached, being separated from the mountains of Esian by the Hvalfiord, and from those towards the north by a flat swampy country extending several miles. It is bounded on the south and west partly by the Faxefiord, and partly by the Borgarfiord. On the southern side the structure of the mountain is exposed almost from top to bottom, in a precipice about 2000 feet high. From Indreholm the beds appear horizontal; but on going round the mountain we found that they dipped towards the north-east, forming a considerable angle with the horizon. From the sea at Indreholm to the foot of the mountain, there is a flat swamp extending more than a mile.

To the height of about 800 feet, the mountain of Akkrefell is composed of beds generally from ten to twenty, and sometimes extending to forty feet thick, of varieties of amygdaloid and tuffa. The latter occurred sometimes not more than a foot in thickness, and was interposed between the beds of amygdaloid. When it was so thin, it much resembled red sandstone. While scrambling among the loose stones, we had met with quantities of slags, for which we were at a loss to account, as we had been told that nothing like lava existed on or near this mountain. Its appearance indicated nothing volcanic; and our surprise on finding any undoubted productions of fire in such a place was increased, when, at the height above mentioned, we saw the under part of a bed completely slaggy, and bearing the most unequivocal marks of no slight operation of fire; and on continuing to ascend, we found every bed, excepting those of tuffa, one of which was at least forty feet thick, presenting the same appearances, and many of them having an amygdaloidal character. Our astonishment was not lessened on discovering a vein of greenstone, about four feet thick, cutting these beds, and having a vitreous coating on its sides, which seems to be common to all the veins of the country. Similar beds occur in the mountains of Esian, where the most important fact connected with them was found in a mass of slag which contained calcareous spar."

The same traveller, in a memoir concerning the Faroe Islands, printed in the 7th volume of the *Edinburgh Transactions*, thus speaks of the trap rocks of that country. "The surfaces of many lavas which I passed over in Iceland, were not unlike coils of rope, or crumpled cloth; an appearance which we should expect to be assumed by any viscid matter in motion. On our first visit to the island of Naalsoe, we observed the surface of a bed of amygdaloid, which had been exposed to a considerable extent by the removal of the bed above, exhibiting an exact picture of the lavas I had seen in Iceland. At first sight, this discovery fixed instantaneous conviction on the minds of those who were with me, some of whom had never seen lava, that heat must have caused the appearance before us. We brought away a number of specimens, which are now before the Society, and which speak a language not to be misunderstood. We afterwards discovered varied examples of this crumpled surface in different parts of the country. In the vicinity of Eyde, in Osteroe, there were many instances in which the matter appeared as if, in a viscid state of fusion, it had flowed and spread itself out." These appearances were seen in different parts of Faroe. Mr Allan, in the same volume, has described the individual minerals found in the trap of Faroe, and expressed his entire conviction of its igneous origin; while, at the same time, he appears at a loss to account for the manner in which heat had operated. Sir George Mackenzie has observed, that "while the great point, the action of heat in the formation of trap rocks, seems to be demonstrated, forming a theory of the manner in which heat has operated in particular cases, is, in a general view, perhaps not absolutely necessary in the present state of geology." Indeed, the farther we advance in the study, the farther we find ourselves from the object of our search, while we continue resolved that either heat or water shall be the sole agent. To us, the most reasonable mode for geologists to follow, appears to be, to consider both heat and water as agents which have been employed in the formation of mineral substances. And we are of opinion that a third agent ought to be added, as one which universally and continually operates, we mean gravitation. The attraction of cohesion, and electricity, may also with propriety be taken into the service; and probably to form a just theory, we should give a share to every agent which can in any degree influence the economy of the globe; the atmosphere, the motion of the earth, magnetism, &c. But at present we must refrain from entering on this subject.

A very remarkable kind of mineralized wood is found on the mountain of Drapuhlid in Iceland. In external appearance, it cannot be distinguished from a mass of charcoal; yet it is very heavy. Chalcedony is observed in some specimens filling small fissures. When the carbonaceous matter is burned, a mass remains, which, when bruised, divides into fibres finer than hair, and resembling asbestos; shewing that the silicious matter had penetrated into the most minute pores of the wood. This substance occurs in a bed of tuf lying under pearl stone. This last substance occurs of a light gray colour, and also dark green approaching to pitch stone. It was found also forming the principal ingredient in a variety of tuf not before described. "It is composed chiefly of masses of black pearlstone, imbedded in a dull blackish green matrix. It contains also masses of amygdaloid, and we found a few nodules of pyrites in it, coated with pitch coal. Pitchstone occurs at Houls, and on the west side of the mountain called Baula.

Surturbrandt.

The surturbrandt of Iceland has not been seen *in situ* by a mineralogist. It has a great resemblance to black oak found in lakes and rivers in many countries. But though capable of being shaped into tables and other articles of furniture, it is not in a condition to be cut by a plane into shavings, being somewhat brittle.

For a description of the individual minerals which occur in these regions, we must refer to the 7th volume of the *Edinburgh Transactions*, and to Sir George Mackenzie's *Travels*. The silicious depositions of the Geysers and other hot springs are very interesting, but are now well known to mineralogists.

Volcanic formation.

The volcanic formation of Iceland is perhaps the most extensive in the world, covering an extent of at least 60,000 square miles. Sir George Mackenzie distinguishes three formations, which are ascribed to the action of internal heat. The oldest is that already described as submarine lavas, which resemble trap rocks more nearly both in position and structure, than any other; and which he supposes to have flowed at the bottom of the sea. The next is a class of lavas to which he has given the name *cavernous*, from its containing numerous cavities, some of them very extensive. This is supposed to be formed of rocks which have been subjected to subterraneous heat, but not removed from their original place. Many of the appearances presented by this class seem to warrant this conclusion in regard to its mode of formation; but the conjecture is thrown out merely to attract the attention of future observers of volcanic countries. The last is the ordinary erupted lava, including ejected substances. Perhaps there is no field in which the investigation of the operations of heat could be carried on with greater facility than in Iceland, the rocks are so well exposed to view. But the shortness of the season in which travelling is practicable, presents a strong obstacle. Yet we hope that some able mineralogists will repeat and extend the observations made by Sir George Mackenzie, and avail themselves of the information afforded by that gentleman.

We understand that the celebrated traveller and mineralogist Baron Von Buch, has carefully examined the Icelandic collection in the cabinet of the Royal Society of Edinburgh, and has the intention of soon communicating to the public the result of his examination of various volcanic countries.

See *Letters on Iceland*, by Von Troil; *Voyage en Islande, fait par ordre de sa Majestè Danois*, par MM. Paulsen et Olafsen; Hooker's *Tour in Iceland*, 1809; *Travels in Iceland*, 1810, by Sir G. S. Mackenzie; *Transactions of the Royal Society of Edinburgh*, vols. iii. and vii. See also the article VOLCANO, which Baron Von Buch has promised to write for this work.

ICHTHYOLOGY.

ICHTHYOLOGY is that department of natural history which treats of FISHES, classifying them according to their forms, ascertaining their haunts, describing their manners, and specifying the uses to which they may be applied. The title of the science is a compound of two Greek words, *ιχθυς a fish*, and *λογος a discourse.*

Fishes belong to that great division of animals, characterised by having an articulated skeleton, a bony cavity containing the brain, a spinal marrow, and red blood. They are thus associated with quadrupeds, birds, and reptiles, from which, however, they may be distinguished by the following characters.

Fishes possess a heart with one auricle and one ventricle. The blood is cold. They are destitute of a windpipe and lungs, breathing by means of peculiar organs termed *gills.* They reside in water, are in general covered with scales, and swim by the assistance of fins.

The ancients regarded as fishes, all animals which seek their food in water, or which reside in that element. Hence we find whales included by older writers among fishes, constituting a subdivision, distinguished by their breathing by means of lungs. But cetaceous animals differ from fishes, not merely in their organs of respiration, but likewise in those of circulation and reproduction. Their heart consists of two auricles and two ventricles, and the blood is warm. They bring forth their young alive, and suckle them.

It is more difficult to draw the line of distinction between fishes and reptiles. The structure of the heart, and the temperature of the blood, are similar in both classes. Reptiles, however, are all furnished with lungs; and although, in a few genera, the young are possessed of gills, yet these organs disappear before the animals arrive at maturity. There are, however, two genera in which the gills are persistent, but the animals belonging to these have digitated feet, and are not likely ever to be confounded with fishes.

The study of this department of natural history is peculiarly difficult. The element in which fishes reside conceals their movements from our view, and prevents us from becoming acquainted with their instincts and habits. In the midst of lakes and rivers, in the depths of the ocean, or in pools on the less frequented shores, they perform unmolested the great operations of nature. Hence the manner of their production, the appearances exhibited by the different sexes, the changes produced by age or season, the artifices they employ to obtain their food, the migrations which they perform, and the limits of their existence, have hitherto been but imperfectly ascertained.

The rarer kinds of fishes, occasionally found on the hooks or in the nets of fishers, are rejected by them as useless, or perhaps exhibited for a few days in the neighbouring village as objects of wonder. They speedily decay, and the only memorials of their existence are preserved in the imperfect traditions of their form. It rarely happens that an intelligent naturalist is on the spot to examine their characters, or to delineate their appearance. But even should there be a person at hand capable of forming a systematic description, still their haunts and habits must remain unknown to us. Of the various species of fishes enumerated by nomenclaturists, perhaps more than the one half are known to us only by their external forms; their food, their instincts, and their functions, remaining unascertained.

The pursuits of the ichthyologist are far from possessing those charms which excite the zeal and admiration of the naturalist in other departments of zoology. It is easy, indeed, to form a collection of these objects, and to preserve their form and characters for scientific purposes; but a museum furnished with such specimens, presents little that is gay or splendid. The colours and lustre of fish fade after death, nor can any process of embalming fix and preserve them. A coating of varnish is often resorted to as a substitute for the natural slimy covering of their skins, and the brush is employed to restore the colours; but specimens prepared in this manner are disregarded by the scientific observer, and to the mere spectator a collection of fishes in wax-work would be equally acceptable. The aspect of some fishes, as the eel for example, is repulsive; while the cold moist surface of others, disgust the fastidious naturalist, or at least lessen his anxiety to examine this portion of animated nature.

These impediments to the study of ichthyology have unquestionably retarded the progress of the science; but we are confident, that the advantages which result from an attentive examination of the subject, may be placed in successful opposition. The rank which fishes hold in the scale of being, as connecting the vertebral with the molluscous animals, is alone sufficient to awaken curiosity; while a considerable degree of interest is excited, by attending to those forms and organs which fit them for residing in the waters. But this department of zoology is not occupied exclusively with matters of mere curiosity or science; the subject is of vast importance in an economical, a commercial, and a national point of view. The inhabitants of this country derive a large portion of their subsistence from the waters; nor could one half of the present population of the country be supported, were access to this great storehouse of life and nourishment cut off.

In confirmation of this assertion, we request the reader to consider the countless numbers of cod, herrings, haddocks, turbot, skate, mackrel, and pilchards, annually furnished to us by the ocean, and the salmon, pikes, perches, and trouts captured in our lakes and rivers. A part of these is consumed by ourselves, and a part exported to foreign countries. These fisheries give employment to many thousands of healthy natives, and are universally considered as the best nurseries of intrepid seamen.

Those who have paid attention to our fisheries, and the legislative enactments by which they are regulated, must be convinced that the subject is imperfectly understood, and acknowledge that many of these statutes originate in our ignorance of the habits and the haunts of the finny tribes. It must therefore appear an object of vast importance to examine the structure of fishes, and trace their manners and economy, with the view of improving the modes of fishing, ascertaining the best frequented grounds, and the periods in which they are in season. These are the objects which the ichthyologist should keep steadily in view, and to the accomplishment of these all his investigations ought to be directed. Hitherto, however, the economical department of the science has been in a great measure overlooked by the systematic inquirer. Occupied, almost exclusively, in ascertaining the position of the fins, or in counting the number of their rays, so as to form the divisions of his arrangement, the ichthyologist seldom condescends to investigate the history or discover the uses of the species. Systematic works in this branch of natural history are therefore seldom consulted by the ordinary inquirer. Disgusted with the mere enumeration of names and external appearances, of which these books consist, he retires to the hut of some old fisherman, and listens with interest to the recital of many anecdotes, illustrative of the different kinds of fish, the best frequented grounds, and the most enticing baits. In such a school he will learn much genuine natural history, mixed perhaps with a little fable.

We wish not to be understood as condemning as useless, the systematic part of ichthyology, but from the heart we condemn that want of attention to the manners of fishes, so conspicuous in the writings of naturalists; a negligence, which has brought the science into discredit, and which may be considered as the principal reason why this department of nature has obtained so few admirers. But we trust the period is at no great distance, in which the ichthyologist will be as anxious to explore the habits of those fishes, with whose specific differences he is already acquainted, as he is at present to add a new species to his list, or effect some trivial revolution in the arrangement of the genera.

In order to present the reader with a general view of the present state of ichthyological science, we propose in the following Chapters, to consider, 1st, The history of the science; 2d, The structure and functions of fishes; 3d, The condition of fishes; and lastly, Their systematic arrangement. We propose to avoid all minute details which would prove uninteresting to the ordinary observer, in order to make room for the developement of those laws which regulate this great class of animated beings.

CHAP. I.

History of Ichthyology.

History.

The history of ichthyology during the first ages of science, may gratify curiosity, but is incapable of yielding instruction. We are in a great measure ignorant of the sources from whence Aristotle obtained his information on this subject; nor do we consider as of great importance those descriptions which he has communicated. Although he treats of the manners and uses of several fishes, and divides the class into cetaceous, cartilaginous, and spinous, his labours did not contribute much to the progress of the science. The writings of Pliny were equally unproductive of advantage. He appears, however, to contemplate fishes as a distinct class of animals, without attempting to define its limits. Ovid, Elian, Athenæus, Oppian, and Ausonius, have contributed a few facts, and several entertaining descriptions. But as we are investigating the history of ichthyology as a branch of the system of nature, we must take our leave of these early writers, and examine the productions of those naturalists who flourished after the revival of letters.

Belon.

Belon, a French physician, deserves to be noticed in this place, as the first modern ichthyologist. In the year 1553, he published his great work *De Aquatilibus*; and in 1555 he produced another work, or rather the ichthyological part of the former, under the title, *La Nature et diversité des Poissons avec leurs Portraits.* Although Belon was more advantageously known as a traveller and ornithologist than as an ichthyologist, his labours in this last department were of service to the science. He did not attempt any general system, but by collecting fishes into groups, he laid the foundation of many natural families or genera. He separated the osseous from the cartilaginous flat fishes, and brought together the different species of sharks into one division. The wooden cuts which accompany the work are not destitute of merit, if we take into consideration the state of the arts at the time.

Rondelet

In the year 1554, Rondelet, a professor of physic at Montpelier, published his work *De Piscibus Marinis.* He has been rather ungraciously treated by his countrymen, for saying, that he was unable for some time to determine on the particular fish with which to begin the descriptions, and that he gave the preference to the *Gilthead,* because it was best known to the ancients and moderns, and highly prized as esculent food. In the course of his observations, he pointed out several distinguishing characters of fishes, which must have contributed to draw the attention of naturalists to their systematic arrangement. In the first four books, he treats of the differences observable among fishes, in regard to their food and haunts, their forms and functions. In the remaining books he describes the different species, in many cases forming these into natural groups. His figures of fishes are superior in execution to those of Belon.

Salvianus

The work of Salvianus, which appeared in the same year at Rome, under the title *Aquatilium Animalium Historiæ liber primus, cum eorundem formis ære excusis,* contained a description of the fishes of Italy to the amount of ninety species. The distribution of the species is destitute of arrangement; but in the description of these he follows a regular plan, treating of the name, characters, station, food, time of spawning, and method of catching of each. It is a matter of regret, that this method of communicating the history of the species has been in a great measure overlooked by succeeding ichthyologists.

Willough
and Ray.

Passing over a number of laborious compilers, who flourished in the end of the sixteenth century, we come now to consider the merits of our countryman Willoughby, and his friend Ray. "These illustrious naturalists," says the intelligent President of the Linnæan Society in his introductory discourse, "laboured together with uncommon ardour in the study of nature, and left scarcely any of her tribes unexplored. But death, which so often disappoints the fairest hopes, cut off the former in the prime of life, before he had digested the materials, to the acquisition of which he had devoted his youth; and they might all have been lost to the world, and his name have perished with them, but for the faithful friendship and truly scientific ardour of Ray. So close was the intercourse between these two naturalists, that it is not easy to assign each his due share of merit. Indeed Ray has been so partial to the fame of his departed friend, and has cherished his memory with such affectionate care, that we are in danger of attributing too much to Mr Willoughby, and too little to himself."

The work of Willoughby, as revised by Ray, was published in folio in 1686, under the title, *De Historia Piscium libri quatuor, jussu et sumptibus Societatis Regiæ Londinensis editi.* This work, the production of a laborious observer and faithful recorder, may be considered as the basis of subsequent discoveries in the physiology of fishes. It is a valuable storehouse of facts, to which the student of ichthyology should frequently resort. The systematic arrangement employed in this work, holds the first place among those systems, which appeared in the end of the seventeenth or beginning of the eighteenth centuries. The following synoptical view of this system, will enable the reader to ascertain the state of the science at the period in which he wrote. The cetaceous fishes form the subject of the second book, the classification of which, as given by our author, we purposely omit.

System of Willoughby.

III. Lib. De piscibus cartilagineis. Ova magna concipiunt.
  1. Sect. De cartilagineis longis.
  2. —— De cartilagineis planis.
  3. —— De cartilagineis oviparis.
IV. Lib. De piscibus oviparis, quorum plerique spinas in carne habent.
  1. Sect. De planis ovip. spin. qui in latus projecti natant.
  2. —— De piscibus anguilliformibus, seu lævibus, lubrices et plerumque oblongis.
  3. —— De piscibus corpore contractiore vel saltem non admodum lubrico, qui pinnis ventralibus carent.
  4. —— De spinosis dictis, quibus pinnarum dorsalium radii omnes molles et flexiles sunt.
  5. —— Pisces spinosi quibus pinnarum dorsalium radii alique aculeati.

Ray afterwards in part improved upon this system, in his *Synopsis Methodica Piscium*, which was published in the year 1713. These two works are regarded by naturalists in general, as having established the claims of ichthyology to rank as a science.

Dale.

Samuel Dale, the intelligent editor of Taylor's History of Harwich, has published a system of fishes in his *Pharmacologia*, which appeared in 1739. He has the merit of introducing several new characters, especially the position of the centre of gravity. The following synoptical view of this system may be useful.

System of Dale.

I. BRANCHIIS RESPIRANTES, CORDE UNICO VENTRICULO PRÆDITO.

Ovipari.

A. Corpore longo et lubrico, squamis quoque carente.
  a. Pinnis ad branchias obtinentes, ventralibus destituti.
  b. Pinnis utroque pari donatis; *i. e.* branchiali et ventrali.
    1. Duabus in dorso pinnis.
    2. Unica in dorso pinna.
B. Corpore contractiore vel saltem non admodum lubrico.
  a. Pinnis non aculeatis.
    1. Unica in dorso pinna.
    2. Duæ in dorso pinnæ eriguntur.
  b. Pinnis aculeatis, duabus in dorso pinnis, anteriore autem spinis radiata.

Vivipari.

A. Cartilaginei.
  a. Longi.
  b. Plani.

II. PULMONE RESPIRANTES, CORDE DUOBUS VENTRICULIS PRÆDITO.

A. Dentati.
  a. Fistulosi.
  b. Non fistulosi.
B. Edentuli.

The inferior divisions, which have been omitted, depend not only upon the position of the centre of gravity, but upon the serratures of the belly, the size of the scales, the structure of the mouth, and the places in which they reside.

Artedi.

Artedi, the friend and countryman of Linnæus, adopted the principles of classification discovered by that great reformer of science, and applied them with success in the arrangement of fishes. But a premature death prevented the completion of his plan. Linnæus collected and arranged his manuscripts, and published them in the year 1738, in two volumes, under the title *Bibliotheca Ichthyologia*, and *Philosophia Ichthyologia.* Another edition, under the same title, made its appearance in 1788 and 1789, by John J. Walbaum, a physician at Lubeck. This work of Artedi is evidently the production of an enlightened naturalist, a laborious student, and an accurate observer. In it the genuine principles of the science were for the first time clearly established. He likewise assigned the true limits of generic characters, and the method of separating species. The work abounds with judicious observations and sound criticisms, and merits an attentive perusal. The following is an outline of his system.

System of Artedi.

PISCES CAUDA PERPENDICULARI.

A. Pinnarum radiis osseis.
  a. Branchiis ossiculatis.
    1. Pinnis inermibus. *Malacopterigii.*

* Pinna dorsi unica in medio fere dorsi.	1. Syngnathus. 2. Cobitis. 3. Cyprinus. 4. Clupæa. 5. Argentina. 6. Exocætus.
** Pinna unica in medio fere dorsi et unica postica dorsi adiposa.	7. Coregonus. 8. Osmerus. 9. Salmo.
*** Pinna unica in extremo dorsi.	10. Esox. 11. Echeneis.
**** Pinna unica pluribusve per totum dorsum extensis.	12. Coryphæna. 13. Ammodytes. 14. Pleuronectes. 15. Stromateus. 16. Gadus. 17. Anarhichas.

***** Pinna unica longa vix a cauda distincta.
  18. Muræna.
  19. Ophidion.

****** Pinna exigua unica in extremo dorsi vel nulla.
  20. Anableps.
  21. Gymnotus.

2. Pinnis osseis, quarum quædam spinosæ. *Acanthopterigii.*

* Capite glabro
  22. Blennius.
  23. Gobius.
  24. Xiphias.
  25. Scomber.
  26. Mugil.
  27. Labrus.
  28. Sparus.
  29. Sciæna.

** Capite aspero
  30. Perca.
  31. Trachinus.
  32. Trigla.
  33. Scorpæna.
  34. Cottus.
  35. Zeus.
  36. Chætodon.
  37. Gasterosteus.

a. Branchiis osseis destitutis.

Branchiostegi
  38. Balistes.
  39. Ostracion.
  40. Cyclopterus.
  41. Lophius.

B. Pinnarum radiis cartilagineis vix a membrana distinctis.

Chondropterigii
  42. Petromyzon.
  43. Acipenser.
  44. Squalus.
  45. Raja.

Pisces cauda horizontali, *including the whales.*

Klein.

Klein made an attempt to classify fishes in his *Historia Piscium Naturalis.* It was published in five parts, the first appearing in the year 1740, and the last in 1749. As this naturalist appeared as the rival of Linnæus, he has too often been condemned by the admirers of the professor of Upsal without sufficient examination. It is true that in the construction of his generic and specific characters, he falls short of the excellence of Artedi or Linnæus, but in the formation of the higher divisions of his system, he exhibits an intimate acquaintance with the external characters of fishes. The following synoptical view will convey an idea of the principles of his system. We have omitted his first division, which contains the cetaceous animals.

System of Klein.

II. Pisces Branchiis occultis.

A. Ad latera.
  a. Pinnata.

1. Spiraculis quinque.
  5. Cynocephalus.
  6. Galeus.
  7. Cestracion.
  8. Rhina.

2. Spiraculo unico.
  9. Batrachus.
  10. Crayracion.
  11. Capriscus.
  12. Conger.

b. Apennia.
  1. Spiraculo unico. 13. Muræna.
  2. Spiraculis septem. 14. Petromyzon.

B. In Thorace.

1. Spiraculis constanter quinque.
  15. Narcacion.
  16. Rhinobatus.
  17. Legobatus.
  18. Dasybatus.

III. Pisces Branchiis apertis.

A. Series I. A partibus notabilibus et corpore anguilliformi.
  a. Capite et ventre notabiles 19. Silurus.
  b. Notabiliter rostrati ore vario.
    1. ore prono capite in solidum rostrum exeunte . 20. Accipenser.
    2. Ore fisso.
      * et labrace, rostro retuso dentibus horridis . 21. Lathargus.
      ** Mandibula superiore in rostrum notabile exeunte 22. Xiphias.
      *** Inferiori mandibula ultra superiorem rostratam producta 23. Mastaaccembalus.
      **** Utraque mandibula equaliter rostrata 24. Psallisostomus.
    3. Ore in rostri tubulosi extremitate 25. Solenostomos.
    4. Capite et cauda rostratus 26. Amphisilien.
  c. Notabiliter plani et oculata.
    1. In dextro latere oculati
      27. Solea.
      28. Passer.
    2. In sinistro latere oculatus 29. Rhombus.
    3. Utrinque oculati .
      30. Rhombotides.
      31. Tetragonopterus.
      32. Platiglossus.
  d. Thoracici notabiliter armati
    33. Cataphractus.
    34. Ceristion.
    35. Centriscus.
  e. Vel sterno vel capite notati instar ricini omnibus corporibus sibique invicem adhærentes
    36. Ocontion.
    37. Echeneis.
  f. Corpore teretiusculo anguillæ adspectum habentes 38. Enchelyopus.

B. Series II. Corpore spisso vel lati, vel carinati et castigati.
  a. Tripterus . . . 39. Callarias.
  b. Pseudotripterus . . 40. Pelamys.
  c. Dipterus.
    1. Pinna secunda cutacea vel adiposa 41. Trutta.
    2. Pinnis ambabus radiatis
      42. Mullus.
      43. Cestreus.
      44. Labrax.
      45. Sphyræna.

** Caudæ proxima .	64. Lucius.
f. Pseumonopterus . . .	65. Pseudopterus.

Linnæus.

We come now to consider the system of the celebrated Linnæus. At first this eminent naturalist adopted the views and arrangements of his friend Artedi. By degrees, however, he unfolded the principles of a new method, which appeared in its most perfect form in the 12th edition of the *Systema Naturæ*, 1766, as follows.

System of Linnæus.

I. Apodes.

Pinnæ ventrales nullæ.

Apertura branchiarum ad latera thoracis	1. Muræna.
Dorsum apterygium . . .	2. Gymnotus.
Cauda aptera	3. Trichiurus.
Dentes rotundati	4. Anarhichas.
Caput corpore angustius . .	5. Ammodytes.
Corpus ensiforme . . .	6. Ophidium.
Corpus ovatum . . .	7. Stromateus.
Rostrum ensiferum . . .	8. Xiphias.

II. Jugulares.

Aperturæ branchiarum ad nucham	9. Callionymus.
Os simum	10. Uranoscopus.
Anus prope pectus . . .	11. Trachinus.
Pinnæ pectorales elongatæ in acumen	12. Gadus.
Pinnæ ventrales didactylæ muticæ	13. Blennius.

III. Thoracici.

Os simum, corpus ensiforme	14. Cepola.
Capitis dorsum planum transversim sulcatum	15. Echeneis.
Caput antice truncato-obtusum	16. Coryphæna.
Pinnæ ventrales coadunatæ inpinnam ovatam	17. Gobius.
Caput corpore latius . .	18. Cottus.
Caput cirris adspersum . .	19. Scorpæna.
Labium superius membrana transversa fornicatum . . .	20. Zeus.
Oculi ambo in latere altero capitis	21. Pleuronectes.
Dentes setacei confertissimi, flexiles	22. Chætodon.
Dentes validi incisores s. molares	23. Sparus.
Pinna dorsalis ramento post spinas notata	24. Labrus.
Pinna dorsalis in fossula recondenda	25. Sciæna.
Opercula branchiarum serrata	26. Perca.
Cauda lateribus carinata; spinæ dorsales distinctæ . .	27. Gasterosteus.
Cauda lateribus carinata: Pinnulæ spuriæ plures . . .	28. Scomber.
Squamæ, etiam capitis, laxæ .	29. Mullus.
Digiti distincti juxta pinnas pectorales	30. Trigla.

IV. Abdominales.

Corpus vix ad caudam angustatam	31. Cobitis.
Caput nudum, osseum scabrum	32. Amia.
Radius 1. pinnæ dorsalis pectoraliumque dentatus . .	33. Silurus.
Caput antice truncatum . .	34. Teuthis.
Corpus cataphractum . . .	35. Loricaria.
Pinna dorsalis postica adiposa	36. Salmo.
Rostrum cylindricum operculo clausile	37. Fistularia.
Mandibula inferior longior, punctata	38. Esox.
Mem. branch. duplex, exteriore minore	39. Elops.
Anus caudæ vicinus . . .	40. Argentina.
Fascia lateralis longitudinalis argentea	41. Atherina.
Mandibula inferior intus carinata	42. Mugil.
Apertura branch. linearis absque operculis . . .	43. Mormyrus.
Pinnæ pectorales longitudine corporis	44. Exocœtus.
Digiti distincti juxta pinnas pectorales	45. Polynemus.
Abdomen carinatum serratum	46. Clupea.
Membrana branchiostega triradiata	47. Cyprinus.

The most remarkable change which we witness in this system, is the removal of the cetacei and cartilaginei of Ray from the class of fishes. The former he has inserted in the class Mammalia, while he has placed the latter among the Amphibia, under the order Nantes. He was induced to assign to these last such a position in his system, in consequence of trusting to the inaccurate observations of Dr Garden of South Carolina, who, from a dissection of the fish called *diodon*, concluded that it possessed both lungs and branchiæ. Subsequent systematic writers have in general restored them to their true place among fishes.

The ichthyologists who preceded Linnæus, invariably endeavoured to employ those characters in the formation of their primary divisions, which indicate some peculiarity of organization, connected with the vital functions. In other words, they attempted to discover a natural method in ichthyology. Linnæus assumed, as the foundation of his system, the relation of the ventral to the pectoral fins, without attempting to point out the influence exercised on the animal economy, by a change of position in these organs. Hence his Orders are all arbitrary and artificial. In the construction of his Genera, he was singularly happy in the choice which he made of characters. Those which are *essential* have been given in the Table; the *natural* character was employed in the system itself. He introduced the use of trivial names, and corrected the specific characters. His terms were classical and expressive, and the whole system bears the stamp of a mighty genius. His genera, it is true, have been divided, in order to form new ones; but how few have equalled this naturalist in the luminous brevity of his characters.

Gronovius.

Gronovius, the cotemporary and friend of Linnæus, published his *Museum Ichthyologicum*, in 2 vols. folio, in the year 1754-6. In this work he attempted the following systematic arrangements.

System of Gronovius.

I. Cauda Horizontali.

Whales.

II. Cauda Perpendiculari.

A. Radiis pinnarum cartilagineis.

Chondropterygii. α. Pinnis ventralibus præsentibus	5. Acipenser. 6. Callorynchus. 7. Squalus. 8. Raja.

1

History.

System of Gronovius.

b. Pinnis ventralibus nullis 9. Petromyzon.

B. Radiis pinnarum osseis.

1. Branchiarum aperturis, foramine exiguo tantum apertis.

Branchiostegi.

a. Pinnis ventralibus nullis
10. Muræna.
11. Gymnotus.
12. Syngnathus.
13. Ostracion.

b. Pinnis ventralibus spuriis

81. Leptocephalus.
82. Gynogaster.

In this system Gronovius has brought back the cetaceous and cartilaginous divisions of Ray. His primary characters are similar to those employed by that illustrious zoologist. Those of a subordinate rank are in part derived from the same source, and from Artedi and Linnæus. As a system, it is inferior to that of Linnæus, since the subordinate characters are liable to exceptions. Like that naturalist, he employs the number of the fins, as a character subordinate to those furnished by their position.

Brunich.

Brunich attempted another system of fishes, which he published in his *Zoologiæ Fundamenta*, (Hafniæ, 1771). It is an attempt to unite the natural method of Ray and his numerous followers, with the artificial system of Linnæus. It appeared at the time when the professor of Upsal was in the meridian of his glory, and was treated with neglect by the admirers of that great man. To us, whose opinions on the merits of these systems are not likely to be influenced by party feelings, the method of Brunich appears equally simple as that of Linnæus, and, in the first tribes, is certainly superior. We add it here, that the reader may judge for himself.

TRIBUS I.

System of Brunich.

Branchiis incompletis. Spiraculis thoracis lateralibus. Aurium foraminibus pone oculos. Pinnis cartilagineis.—CHONDROPTERIGII.

1. Petromyzon.
2. Raja.
3. Squalus.
4. Chimæra.
5. Acipenser.

TRIBUS. II.

Branchiis incompletis. Apertura thoracis linearis. Pinnis membranaceis radiatis. Corpore sæpius cataphracto vel muricato. BRANCHIOSTEGI.

A. Pinnis ventralibus nullis.
6. Syngnathus.
7. Ostracion.
8. Balistes.
9. Tetrodon.
10. Diodon.

B. Pinnis ventralibus presentibus.

12. Cyclopterus.
13. Centriscus.
14. Pegasus.

TRIBUS III.

Branchiis completis. Apertura thoracis hiante, Pinnis membranaceis radiatis; ventralibus nullis; corpore sepius alepedoto.—APODES.

System of Brunich.

15. Xiphias.
16. Anarhichas.
17. Ammodytes.
18. Trichiurus.
19. Stromateus.
20. Muræna.
21. Ophidion.
22. Gymnotus.

TRIBUS IV.

Branchiis completis. Apertura thoracis hiante; pinnis membranaceis radiatis; ventralibus sub jugulo; corpore squamis minutis tecto vel nudo. JUGULARES.

23. Lepadogaster.
24. Blennius.
25. Gadus.
26. Uranoscopus.
27. Callionymus.
28. Trachinus.

TRIBUS V.

Branchiis completis. Apertura thoracis hiante; pinnis membranaceis radiatis; ventralibus in thorace; corpore sepius squamoso quam alepidoto.—THORACICI.

- A. Malacopterigii.
  - 29. Cepola.
  - 30. Coryphæna.
  - 31. Pleuronectes.
  - 32. Echeneis.
- B. Acanthopterigii.
  - 33. Gobius.
  - 34. Sparus.
  - 35. Labrus.
  - 36. Mullus.
  - 37. Scomber.
  - 38. Trigla.
  - 39. Chætodon.
  - 40. Perca.
  - 41. Gasterosteus.
  - 42. Scorpæna.
  - 43. Cottus.
  - 44. Zeus.

TRIBUS VI.

Branchiis completis. Apertura thoracis hiante; pinnis membranaceis radiatis, ventralibus in abdomine; corpore squamato loricato vel alepidoto.—ABDOMINALES.

- A. Malacopterigii.
  - 45. Salmo.
  - 46. Argentina.
  - 47. Amia.
  - 48. Fistularia.
  - 49. Esox.
  - 50. Cobitis.
  - 51. Cyprinus.
  - 52. Exocætus.
  - 53. Clupea.
  - 54 Mormyrus.
  - 55. Atherina.
- B. Acanthopterigii.
  - 56. Silurus.
  - 57. Loricaria.
  - 58. Theutis.
  - 59. Elops.
  - 60. Polynemus.
  - 61. Mugil.

The four last tribes of this system are obviously those of Linnæus, with the introduction of a subordinate character from Ray. We must, however, observe, that among fishes whose fins have soft articulated rays, or are malacopterigious, several species have been inserted by ichthyologists, which were entitled to a place among those with spinous rays, termed Acanthopterigious. Thus many species of the genus Pleuronectes (but not all of them) have a strong spine in front of the anal fin; and in the genus Cyprinus, both the carpio and barbus have one serrated spinous ray in the dorsal fin. The species of these two genera are still retained among the malacopterigious fishes, and could not be far removed from their present situation, without destroying the natural links of the species. Such inconsistencies will be found in all systems, where characters are employed which exercise but a feeble influence on the animal functions.

Gouan.

Professor Gouan of Montpellier, made another attempt on the classification of fishes, in his *Histoire des Poissons*. It is essentially the same as that of Brunich, with some slight alterations in the genera in the branchiostigous divisions.

Scopoli.

Scopoli in his *Introductio ad Historiam Naturalem*, (1777,) attempted a new system, founded on the position of the anus. Linnæus had previously employed the same character in the formation of two genera in his system, namely Trachinus and Argentina. But Scopoli elevated it to the rank of a primary character, and divided fishes into the three following classes. 1. Ano inferiore sive caudæ plus minus approximato. 2. Ano superiore, capite plus, minus approximato. 3. Ano medio. The subordinate characters are those which had been employed by former authors. The efforts of these two naturalists to produce systems, were never treated with much attention.

Bloch.

In the year 1785, the splendid work of Bloch on fishes, made its appearance both in German and French. The system is professedly that of Linnæus, with additions to the number of genera warranted by the researches of the author. The descriptions and figures, which are in general of the real size, are from nature, and the economical history of the species is given in detail. Walbaum with propriety styles this work, *Opus sine pari*.

Bonnaterre.

The ichthyological department of the *Encyclopedie Methodique* was undertaken by Bonnaterre, and published in the year 1788. This author, in the systematic part of the subject, followed the method of Linnæus. His introductory matter, however, is more valuable than the systematic part. He has collected with care, the principal facts respecting the anatomy and functions of fishes, and has arranged and defined the characters which he employs. He has added a number of good figures of fishes, chiefly copies from other works.

Cuvier.

In the year 1800, the "Lectures on Comparative Anatomy," by Cuvier made their appearance. Independent of the important contributions to the physiology of fishes, this author has attempted a classification of those animals, which merits the consideration of naturalists. The following outline, in which the genera are omitted for want of room, may be acceptable to the systematic enquirer.

System of Cuvier.

History.

System of Cuvier.

CARTILAGINOUS FISHES . . .	Fixed Branchiæ, Chondropterigii .	Round mouth at the end of the nose or snout.	
		Transverse mouth under the snout.	
	Free Branchiæ, Branchiostegi . . .	Transverse mouth under the snout; teeth.	
		——— no teeth.	
		Mouth at the end of the nose; no teeth.	
		——— teeth.	
		The bones of the jaws answering instead of teeth.	
		Mouth very wide; a number of small teeth.	
OSSEOUS FISHES	Apodes	Mouth at the end of the nose.	
		Mouth under the nose.	
	Jugulares	Head unarmed.	
		Head armed.	
	Thoracici	Dorsal fins partly spinous; head armed.	
		Dorsal fins partly spinous; head unarmed	Two dorsal fins.
			One dorsal fin.
		Bones of the jaws naked, and answering instead of teeth.	
		Two eyes on the same side.	
		The body very long.	
		A furrowed discus on the head.	
	Abdominales	No operculum to the branchiæ.	
		No teeth.	
		Sharp teeth; no cirri.	
		Head depressed; cirri.	
		Spines free on the back.	
		Mouth at the end of the nose.	

Several natural families are formed by this author, and we hope he will add to the number in the second edition of his work.

De la Cepede.

In the year 1803, De la Cepede completed his *Histoire Naturelle des Poissons,* in five volumes. The opportunities of investigating the subject of ichthyology enjoyed by this author were valuable, and he has availed himself of these with very great diligence and success. He had access to the best furnished museum in Europe, formed from the spoils of the collections of those countries which France had subjugated. Before giving our opinion of the execution of the systematic part of the author's plan, we shall lay a sketch of it before our readers.

System of De la Cepede.

System of De la Cepede.

Le sang rouge, des vertèbres, des branchies au lieu de poumons.

			30.	2. Jugulaires. 0
			31.	3. Thoracins. 0
			32.	4. Abdominaux. 0

The reader will perceive, that the primary characters are those of Ray. The secondary characters, depending on the structure of the appendages of the gills, may be considered as in a great measure his own; while those of a third rank belong to the Linnæan system. It may perhaps surprise an English reader to be informed, that of the thirty orders which are here constituted, only seventeen can be employed at present, the remaining fifteen having no examples in nature. To these last orders, I have added a cypher in the synoptical view.

Every ichthyologist will allow that many fishes must exist in nature which have never come under the inspection of the naturalist; many links in the chain are still wanting; so that our systems, for the present, must be imperfect. But we can assign no other motive, in thus constructing orders which have no ascertained existence, than a desire to anticipate discovery, and to exhibit a confident reliance on the perfection of the systematic principles employed.

The characters which he uses in the construction of his genera, are derived from various sources. Thus, his genus Prionotus, is separated from that of Trigla, by the serrated spines between the dorsal fins of the former. Serrasalmus, is separated from Salmo, in consequence of a serrated abdomen. The number of the dorsal fins separates Lutanus from Centropomus. The size of the dorsal fins forms the distinction between Bodianus and Tænianotus. It is rather singular that this author takes no notice of the number of rays in the gill flap as a generic character, while the presence of that organ furnishes him with one of his primary characters.

The names of his genera are in many instances exceptionable, and appear to have been constructed in open violation of the acknowledged rules of the science of zoology. The following maxim of Artedi, *Nomina generica, ex uno nomine generico fracto et altero integro composita exulent,* is overlooked in the following examples of hybrid names, among many which might be produced: Gobiesox, Scomberesox, and Murænoblenna. The propriety of adhering to this rule of Artedi, must appear evident, when we consider, that such names indicate ambiguity or doubt with respect to their characters, "innuunt enim ambiguitatem quandam, ut incertum sit ad quodnam genus piscis proprie pertinat." Another rule in ichthyology, "*Nomina generica desinientia in* oides *non probari debent,*" is equally despised, although Artedi justifies its value by saying, "quia aliud genus innuunt vel aliud alludunt, cui hoc in *oides* desinens, simile erit, et nullam ulteriorem originem vel causam suæ denominationis habent." Thus, Lacepede has the following genera: Mugil Mugiloides, Gobius Gobioides, Coryphæna Coryphænoides, Scomber Scomberoides, Muræna Murænoides. There is a third rule given by Artedi, and equally entitled to the attention of the ichthyologist, which La Cepede likewise overlooks.—"*Nomina generica, quæ non sunt originis Latinæ vel Græcæ proscribantur.*" Thus we have the following barbarous names, *Misgurnus,* formed from Misgurne, the Bavarian provincial name of Cobitis fossilis of Linnæus, and the only known species of the genus Makaira, the name of a fish known at Rochelle. There is likewise a genus *Ompok,* a name attached to a dried fish in the Dutch collection, and provincial. The similarity in the sound, between many of the genera of this author, will inevitably lead to confusion. Thus we have Holocentrus and Holocanthus, Pomacentrus and Pomacanthus, Callionymus and Calliomorus, Acanthurus and Acanthopodus, and a host of other genera with names so nearly alike, that we might be led to suppose the author formed them purposely to perplex. We cannot close our observations on the genera of this author, without adding, that all generic names taken from objects in the other classes of nature, ought to have been rejected; such, for example, as Eques, Gallus, Hydrargirus.

In the construction of his species, there is perhaps too strong a desire to increase their number, in the absence of all prominent characters. This, we fear, has been the case in the genus Salmo, Labrus, and some others, where the limits of the species are ill defined. He has been too liberal in employing the names of individuals, as trivial names to his species. Thus we have three different species in the system named in honour of his wife, who does not appear to have been particularly attached to any branch of natural history. We can have no objections to an author dedicating his work to his wife, as La Cepede has done; but we object to the naming of species, ascertained by the labours of others, in honour of any female friend. In France, an author may gain credit for his sensibility and love, by so doing, but to our colder temperament, it seems to be affectation. In many instances, our author changes the received trivial names, bestowing upon them new ones of his own, without even assigning any reason for doing so. This takes place in almost every extensive genus of the system, and merits the severest censure. The French naturalists, it is true, have not scrupled to violate established maxims in science, in order to form a *French system.* This seems to have been the reason why La Cepede abandoned the principles of Artedi in the construction of his genera, and disregarded the dogmas of the Linnæan school. But the French systems, like all others, must submit to the test of sound principles; and when tried by these, whoever shall attempt to restore to its Linnæan purity this department of zoology, must cancel multitudes of the names of La Cepede. We may add, that the descriptions are often swelled by vague analogies, and are in too many instances destitute of precision.

These remarks have extended perhaps too far; but as the system is at present the most popular in Europe, we have judged it expedient to state our undisguised sentiments as to its merits. It abounds in faults, but it is not destitute of excellence. A vast mass of facts is collected, many species are for the first time described, many new characters are unfolded, and the work upon the whole is the most complete view of ichthyology extant. Figures of the new or rarer species are given. These, however, are inferior in every respect to those of Bloch.

Shaw.

The ichthyological part of the *General Zoology* by Dr Shaw, appeared in two volumes, in the years 1803-4. We sincerely regret that it is not in our power to bestow any praise on this work. The text is a very meagre compilation, chiefly from the writings of Bloch and La Cepede; and the figures which accompany the work, are principally copied from the same sources.

In the preceding historical review of ichthyological writers, in which we have endeavoured to mark the progress of the science, the reader must have perceived the great difference of opinion, with respect to the value of the characters employed in classification. The organs of motion are regarded by some as holding the first rank, while those of respiration are preferred by others.

These circumstances indicate the infant state of the science, and point out the propriety of an anatomical investigation of the whole tribe.

We are still in want of accurate representations of many species of fishes. The figures which we meet with, often bear but a remote resemblance to the objects themselves. When a painter, ignorant of natural history, is employed to delineate a fish, (or any other animal), he is apt to overlook the most important characters, unless these are very obvious. He rests satisfied if he produces a general resemblance. Hence the peculiar shape of the fins is often sacrificed to the desire of avoiding sharp angles, and spots, punctures, or streaks, are omitted as useless, or as spoiling the beauty of the drawing. These figures, in passing afterwards through the hands of the engraver, are still farther altered to suit professional taste, so that the figures in works on natural history are often imperfect representations. Hence naturalists should study the art of drawing, and carefully inspect the strokes of the engraver, if fidelity in representation be the object in view.

Writers on British ichthyology.

Before closing these short notices of the principal writers on fishes, we propose to add a few observations on the labours of those who have contributed to the advancement of British ichthyology. This branch of natural history has never been very popular in Britain, and at present is in a great measure neglected. Merret, in his *Pinax rerum Naturalium Britannicarum*, London, 1667, is the first who arranged systematically our native fishes. He distributed them into the following classes: I. Pisces pelagii squamosi. II. Pelagii læves. III. Marini saxatiles. IV. Squamosi in mari et in fluminibus. V. Fluviatiles squamosi. VI. Fluviatiles læves. He has enumerated about 76 species. He acknowledges the assistance which he derived from Turner in his letter to Gesner. His references are chiefly to the works of Gesner and Aldrovandus; and he has added a number of provincial names. Taking all circumstances into consideration, this little work deserves great praise.

The labours of Willoughby and Ray, which we have already mentioned with respect, contributed to advance the science of ichthyology in this country, by the introduction of a more determinate nomenclature, and a more accurate definition of species.

From the days of Ray until the appearance of Pennant, no systematic British ichthyologist had appeared. In the year 1776, that naturalist published his British Zoology. The third volume of this work treats of our native fishes, amounting to one hundred and fifty-two species, exclusive of the cetacea. The system which he follows is the Linnæan, with the addition of the cartilaginei of Ray. He does not confine himself to mere descriptions; he notices the habits and uses of the particular species. The figures are upon the whole respectable. This work contributed to diffuse a taste for the study of zoology in this country, and still continues to maintain that reputation which its general accuracy, and pleasing style, deservedly procured. A second edition made its appearance two years ago, edited by a son of the author's. It contains a few additions, compiled from authentic sources.

The *Synopsis of the Natural History of Great Britain and Ireland*, by Berkenhout, merits a place in this catalogue. The first edition appeared in the year 1769, and the second in the year 1795. In the first volume the British fishes are enumerated, amounting to 157 species, and arranged according to the Linnæan method. The specific characters are short, but judiciously selected.

In the year 1802, Mr Stewart of Edinburgh published his *Elements of Natural History*, in which he enumerates the British species of fishes. This work has lately been revised by the author, and several new species have been added to his list.

Mr Donovan completed, in 1808, five volumes of his *Natural History of British Fishes*. This work contains coloured representations of 119 species. The figures are faithful representations, and the descriptions abound in sound criticisms and important illustrations. He is perhaps deficient in his account of the external characters of the species. This production is a valuable book of reference, and ought to be frequently consulted by the student. We may add that he has swelled the list of British fishes by the discovery of many new and curious species.

The *British Fauna*, by Turton, was published in 1807, previous to the completion of the preceding work. In this small volume 168 species are described. It is a very useful compilation, chiefly on account of its convenient size for the pocket.

Besides these systematic writers on British ichthyology, several naturalists, by describing the fishes of particular districts, have rendered important service to the science.

In the work of T. Caius *De Canibus Britannicis*, (Lond. 1570,) contains notices respecting a few species of British fishes, such as the xiphias, the trachurus, the acus, and a few others.

In 1684, Sir Robert Sibbald published his *Prodromus Historiæ Naturalis, sive Scotia Illustrata.* In this work the fishes of Scotland are described and enumerated; and, considering the state of the science at the time, the catalogue is an extensive one. The same author enlarges on the fishes of the Frith of Forth in his *History of Fife and Kinross.*

The topographical labours of Plott merit respectful mention; and in his *Histories of Oxfordshire and Staffordshire*, he has not overlooked the fishes of these districts. The history of the former county appeared in 1676, and that of the latter in 1686.

In 1698, Martin published his *Description of the Western Islands of Scotland*, in which he notices the ichthyological productions of those seas, but in a very cursory manner.

Wallace, in 1700, published his *Account of the Orkney Islands*, in which he noticed a few of the more common fishes of that country.

The British student of zoology must be familiar with the name of Borlase. His *Natural History of Cornwall*, published in 1758, is generally quoted as a book of reference, and contributed to advance our knowledge of British fishes. Several new species were published for the first time from the drawings of the Rev. Mr Iago, minister of Loo.

Several remarks, illustrative of Irish ichthyology, appear in Rutty's *Natural History of the County of Dublin*, 1772. Smith, in his county histories of Kerry, Waterford, Cork, and Down, had communicated previously a few imperfect notices regarding the fishes of those districts.

In the year 1811, the first volume of the *Memoirs of the Wernerian Natural History Society of Edinburgh* appeared before the public, containing two papers illustrative of British ichthyology. The first is the production of the late eminent zoologist Montagu, in which he gives an account of five rare species of British fishes, to be afterwards taken notice of. The second paper is from the pen of the secretary, Mr Neill. It contains a list of the fishes of the Forth, and the lakes and rivers in the neighbourhood of Edinburgh, which have been observed by the author. The species amount to 76 in number, and among these there is one new British species.

The last author whom we shall mention as having contributed to extend our knowledge of the distribution of British fishes, is the late Rev. George Low, minister of Birsa and Hara. The *Fauna Orcadensis,* which he left behind him in MS. was published in the year 1813, and contains an extensive list of the fishes which the author observed in the seas around the islands of Orkney.

CHAP. II.

Structure and Functions of Fishes.

Structure and functions.

As fishes are destined to live in water, we may expect to find all their organs constructed in such a manner, as to accommodate themselves to the properties of that element. We propose to examine these organs in succession, and to bestow attention at the same time to the functions which they perform. By treating the subject in this manner, repetitions will be avoided, and the general reader assisted in comprehending the economy of this important class of animated beings.

Sect. I. *Organs of Support.*

Organs of support.

The bones of fishes vary in form, proportion, and number, according to the species. The skeleton is more complicated than that of man, and is difficult to prepare and preserve. Hence the osteology of fishes is a subject but little attended to by naturalists. Avoiding all minute details, we propose to consider the skeleton, as consisting of a cranium, spine, and ribs.

As the *cranium* of fishes is covered with skin only, its form is easily ascertained, and it exhibits remarkable differences in shape according to the species. In all the species it is large in proportion to the size of the body. The cranium of osseous fishes consists of a great number of separate pieces. These amount to eighty in the perch. But as these bones are soon ossified together, it becomes very difficult to trace the original lines of separation in aged individuals. The occiput appears like a vertical truncation of the cranium, and is united to the spine by a single tubercle placed below the foramen. The motion of the head is very limited in every direction. In some of the cartilaginous fishes, the head is joined to the vertebral column by two condyles; but this articulation is equally incapable of extensive motion as the former.

The *vertebral column* is either cylindrical, angular, or compressed. The vertebræ may readily be distinguished from those belonging to the higher classes, by the peculiar form which they exhibit. The body of the vertebra is of a cylindrical figure, with a funnel-shaped depression at each end. It consists of concentric rings, which are supposed by some to increase in number with the age of the animal. The vertebræ are destitute of articular processes, and when in union, form throughout the whole column cavities composed of two cones, joined at the base. These cones contain a cartilaginous substance formed of concentric fibres, of which those next the centre are the softest. By means of this cartilage the vertebræ are united, and upon it they perform all their movements. In the cartilaginous fishes all the vertebræ are consolidated together, so that the spinous processes can only be distinguished.

The vertebræ may be divided into the cervical, dorsal, and caudal. In osseous fishes, the *cervical vertebræ* are in general wanting, although in some cases they exist, as in the herring, to the number of four. In the cartilaginous kinds, they are ossified into one piece. The *dorsal vertebræ* are easily recognised, by wanting processes on the inferior part. These have generally on the sides transverse processes, to which the ribs are attached. The *caudal vertebræ* are possessed of spinous processes, both on the superior and inferior surfaces. In those fish which are flat these are very long, as in the flounders. The first caudal vertebra is in general of a peculiar shape. The cavity of the trunk is terminated by its inferior process. In the flounders it is large, round in the fore part, and terminated below by a sort of spine. The last caudal vertebra is however more remarkable than the first. It is almost always of a triangular form, flat, and placed vertically. Upon its posterior extremity it bears articular impressions, which correspond to the small and delicate bones of the fin of the tail.

The number of the bones of the vertebral column in different species being exceedingly various, suggested to Artedi the use of this character in the separation of nearly allied species. Among the species of the genus Cyprinus, for example, a difference in the number of vertebræ has been observed to the amount of fourteen. In ascertaining this character, Artedi recommends the greatest circumspection. The fish should be boiled, the fleshy parts separated, and the vertebræ detached from one another, and these counted two or three times in succession to prevent mistakes. This character is of great use, as it is not liable to variation, individuals of the same species exhibiting the same number of vertebræ in all the stages of their growth.

The number and size of the *ribs* are likewise extremely various. The cartilaginous fishes may be considered as destitute of true ribs. Where they exist, as in the osseous fishes, they are articulated to the body of the vertebræ, or to the spinous processes. They are forked in some fishes, and in others double; that is, two ribs proceed from each side of every vertebra. In the genus Cyprinus they are of a compressed shape; in the cod they are round; and in the herring like bristles.

The number of the ribs likewise furnishes a character in the discrimination of species, which may be safely relied on in the absence of more obvious characters.

Besides these bones which we have enumerated, there are many more osseous spiculæ, which serve to support the fins, and to strengthen the muscles. Indeed the existence of numerous bones, unconnected with the skeleton, is a distinguishing character of the osteology of fishes, and these we shall afterwards consider in our account of the different purposes to which they are subservient.

The composition of the bones of fishes has never been investigated with sufficient care. It is well known, that they never acquire so great a degree of hardness and rigidity as the bones of the mammalia or birds: hence we may safely conclude from the facts connected with the process of ossification in other animals, that the bones of fishes abound in gelatinous and cartilaginous matter, while the portion of earthy or saline matter is small. The earthy salts are phosphate and carbonate of lime, and the phosphate of magnesia, the former predominating in quantity. In one division of fishes, termed the *cartilaginous*, the proportion of earthy matter is so small, that the bones never become indurated, but continue in all the periods of the life of the fish soft and flexible. These animals are therefore supposed to grow during the whole course of their existence.

When the bones of some fishes are boiled in water, they undergo a change of colour. This circumstance is well illustrated in the case of the gar-fish, or sea pike, (*Esox belone*,) whose bones by boiling become of a grass green colour; and in the bones of the viviparous blenny, which experience a similar change. This alteration of colour has fostered some of the prejudices of the vulgar, but has failed to arrest the attention of the chemist.

The bones of fishes when reduced to powder, are mixed up with farinaceous substances, and used instead of bread by some of the northern nations. In Norway, and even in some of the remote districts of our own country, fish bones are given as food for cows, and are greedily devoured by them.

Sect. II. *Organs of Protection.*

Organs of protection.

Under this head, it is our intention to consider the skin, the scales, and the spines of fishes. The *skin* of fishes consists, as in the other vertebral animals, of a true skin, a rete mucosum, and a cuticle. The *cutis*, or true skin of fishes, is remarkably thick in those species which have small scales; while in those which have large scales, it frequently assumes the appearance of a thin membrane. It is much more closely attached to the muscles in this tribe than in any of the other vertebral animals. This organ in the *gadi*, for example, consists almost entirely of gelatine, and hence is much esteemed as an article of food, and is used also in fining, as a substitute for isinglass. Eel skins are likewise used in the manufacture of size, in consequence of the gelatine which they contain.

In the higher classes of vertebral animals, there is an organ termed the *corpus papillare*, or the villous surface of the skin, in which the sense of touch is supposed more particularly to reside. Fishes, however, are destitute of this organ; and hence anatomists have concluded, that these animals are possessed of this sense in a very imperfect degree.

Intermediate between the true skin and the cuticle, is situated the *rete mucosum*. It consists of a mucous layer, in which the colouring matter of the skin resides. In the animals which we are now considering, this layer is remarkable for the brilliant tints which it exhibits, communicating to the scales all their metallic lustre.

The *cuticle*, or external layer of the skin, appears in fishes in a soft state, and, in many instances, is a simple mucous substance enveloping the body. It is detached at certain seasons of the year in large pieces.

The *scales* are implanted in the cuticle, and in their position and use resemble the hairs on the bodies of quadrupeds. They cover the body of fishes like tiles on the roof of a house, pointing backwards. The posterior edge, which in general is free, is usually crescent-shaped, fringed in some species, and smooth in others. By means of a lens, longitudinal ribs may be perceived finely decussated by transverse striæ. These ribs sometimes radiate from the centre, and the crossing striæ are concentric. When macerated in weak acids, they are found to consist of alternate layers of membrane and phosphate of lime, and hence are supposed to increase in every direction by the addition of new layers.

Instead of imbricated scales, some fishes are protected by *osseous plates*, covered, like the scales, by the cuticle, and presenting an even surface. Among some of the sharks, as the *Squalus acanthias*, instead of scales there are flat bent bristly laminæ; and in the remora there are hard rough tubercles. These osseous plates in the sturgeon, resemble in shape the shell of a limpet.

These scales may be considered as the ordinary armature of fishes. They guard their bodies from external injury, and, when rubbed off by accident, they are reproduced.

The naturalist employs the appearances exhibited by the scales, as a character in the discrimination of nearly allied species. The form, the surface, and the size of the scales, are chiefly used for this purpose, although the disposition of the longitudinal and the transverse rays, together with the condition of the margin, would furnish more permanent marks. The scales in the description of a fish, are likewise considered in regard to their adhesion to the skin. Thus some scales, which adhere but slightly, are said to be deciduous; while others, which cannot be rubbed off but with difficulty, are termed tenacious or adhesive.

Besides the scales, many fishes are furnished with spinous processes. These sometimes accompany the fins; while in other instances they appear as the armature of the head and cheeks. They appear to be of the same consistence and composition as horn. Those found on the head are in general fixed; but those connected with the fins are moved by peculiar muscles. These organs may be considered as defensive weapons, and act, in some instances, not merely by their form and consistence, but by some *venomous* secretion by which they are covered. Thus the common weever (*Trachinus draco*) inflicts a wound with the spines of the first dorsal fin, often followed by violent burning pains, inflammation, and swellings; so that the fishermen are in the practice of cutting off the offensive organ before they bring the fish to market. The spines of the *Squalus acanthias*, or piked dog-fish, is likewise considered by fishermen as capable of inflicting a dangerous wound.

The fishes furnished with spinous rays in the fins, were, at a very early period, separated from those with soft rays. They were termed *Acanthopterygii* by Artedi. The fishes furnished with spines on the head or cheeks, have been subdivided by La Cepede into several genera, from the characters furnished by these organs.

Sect. III. *Organs of Sensation.*

Organs of sensation.

In attending to the organs of sensation in fishes, the condition of the *brain* demands our first consideration. We have already stated, that the head is large in proportion to the size of the body; but with regard to the brain, the reverse of this appears to be the case. It does not completely fill the cavity of the cranium destined for its reception, the surrounding space being occupied by a salt fluid. It bears a much smaller proportion to the size of the body, than we find in the higher classes of animals. The following Table of these proportions in a few fishes is given by Cuvier.

White shark (*Squalus carcharias*)	$\frac{1}{2495}$
Great dog-fish (*Squalus canicula*)	$\frac{1}{1344}$
Tunny	$\frac{1}{37440}$
Pike	$\frac{1}{1305}$
Carp	$\frac{1}{560}$
Silurus glanis	$\frac{1}{1887}$

The brain of fishes is of a less compact texture than that of the superior animals, and in some species is almost fluid. In structure, however, it is nearly the same, although characterised by a few constant marks. The subdivisions of the brain and cerebellum, or their tubercles and lobes, are more numerous than in the mammalia and birds. In one genus of fishes, the Gadus, Dr Monro (*Structure and Physiology of Fishes*, Edin. 1785, p. 44.) found spheroidal bodies between the dura and pia mater, and covering the greater part of their nerves, like a coat of mail, in their course towards the organs to which they are destined. He was unable to ascertain their use.

The *spinal marrow* in fishes, instead of being conveyed in a vertebral canal, as in the mammalia, passes through the space formed by the superior processes of the vertebra. Like the other nerves of fishes, the size of the spinal marrow is in proportion to the size of the body, not to the brain from which it proceeds.

Having offered these few observations on the brain, we now proceed to consider the organs of the five senses, adverting to their structure, their functions, and their importance in the classification of fishes.

Smelling.

1. *Organs of smell.* The external organs of smell present several remarkable differences, according to the species, varying in number, shape, and position. In many fishes the nostrils are single, while in others they are divided at the surface by a transverse membrane, and thus exhibit the appearance of being double on each side. They likewise vary in shape, being round in the cod-fish, oval in the conger-eel, and oblong in others. They are placed in the snout in many fishes, near the eyes in some, and between the eyes and the snout in others. Where the openings are double on each side, these are either placed contiguous to each other, as in the carp, or at a little distance, as in the perch. The nostrils in some instances appear like short tubes.

The nasal openings are furnished with a few muscular fibres, which are capable of executing a limited contractile motion. This motion, however, in living fishes, can seldom be perceived.

Proceeding to the examination of the inside of the nostril, we may observe, that in the sharks and skates the nasal laminæ are placed parallel to each other on both sides of a large lamina, which extends from one end of the fossa to the other, and consist of folds of the pituitary membrane. In the other fishes, whether cartilaginous or osseous, the laminæ proceed like radii from an elevated and round tubercle. The pituitary membrane in some fishes, as in the pike, is furnished with reticular ramifications of black vessels, but in the greater number of fishes these vessels are red. Between these are situated some small papillæ, which pour out a thick mucilage.

The *olfactory nerves*, at their origin, form swellings or knots, so large as frequently to have been mistaken for the real brain. These tubercles in skates and sharks are united into one homogeneous medullary mass, from each of the lateral parts of which the olfactory nerves arise. In the species of the genera Pleuronectes, Clupea, Esox, Perca, and Salmo, there are two pair of tubercles, the anterior of which is smaller than the other.

In the cartilaginous fishes, as the skate and shark, the olfactory nerve is very soft. It is, in them, a bulb which passes obliquely forward towards the nares, which are at a greater or less distance from the brain according to the species. The spinous fishes have the olfactory nerve very long and slender. In those which have the snout elongated, this nerve is received into a cartilaginous tube. In those with short snouts, the nerve is surrounded by a fine membrane only, which appears to be the same as that which contains the fat or oily humour that covers the brain. In the haddock, and some other fishes, the olfactory nerve, in its course from the brain to the nose, passes through a cineritious ball, which resembles the cineritious matter connected in our body to the olfactory nerve within the cranium.

When the olfactory nerve arrives behind the folded membrane which we have described, it is dilated to be applied to the whole of its internal and convex surface. In some fishes no previous enlargement takes place, while in others the nerve swells into a real ganglion. When expanded, it has been compared to the retina, but the filaments of which it is composed are more distinct.

The sense of smell in fishes is supposed by many to furnish them with the most delicate tests, for searching after and distinguishing their food. Dr Shaw (*General Zoology*, vol. iii. p. 9.) states, that "if you throw a fresh worm into the water, a fish shall distinguish it at a considerable distance; and that this is not done by the eye is plain from observing, that after the same worm has been a considerable time in the water, and lost its smell, no fishes will come near it; but if you take out the bait, and make several little incisions into it, so as to let out more of the odoriferous effluvia, it shall have the same effect as formerly. Now it is certain, that had the animals discovered this bait with their eyes, they would have come equally to it in both cases. In consequence of their smell being the principal means they have of discovering their food, we may frequently observe them allowing themselves to be carried down with the stream, that they may ascend again leisurely against the current of the water; thus the odoriferous particles swimming in that medium, being applied more forcibly to their organs of smell, produce a stronger sensation." We do not presume to dispute the accuracy of these observations, but we may observe, that the well known voraciousness of fishes, the eagerness with which they will seize a metal button, or any glittering object, the whole art of artificial bait and fly-fishing, all seem to point out the organ of sight as the principal instrument by which they discover their food. Besides, the organs of smelling are by no means favourably situated for receiving quickly the impressions new objects are calculated to produce. In the chondropterygii the nares communicate by a groove with the angles of the mouth, but in general the organs of smell have no communication with those of mastication or respiration; and as the external openings are narrow, and but ill supplied with muscles, we are at a loss to conceive in what manner the water impregnated with odoriferous particles is thus rapidly applied to the extremities of the olfactory nerve. Alternate absorption and ejection of the water have never been observed. The same water we know must pass through the mouth, and be spread over the extended surface of the gills; so that we may presume, until farther light be thrown on the subject, that these latter organs may likewise contribute to warn the fish of the presence or absence of salutary or noxious impregnations.

The organs of smell furnish the ichthyologist with some important characters in the description of the species. These have hitherto been too much neglected, as they have the advantage of being permanent.

Seeing.

2. *Organs of sight.* The eyes of fishes, like all other red-blooded animals, are two in number. They vary greatly in position, both being, in some species, on the

same side of the head, as in flounders, while in others they are nearly vertical. In general, however, they are placed one on each side of the head. The eyes of fishes are larger in proportion to the size of their bodies than in quadrupeds, as we find the eye of the cod-fish equal in size to that of an ox.

Fishes in general are destitute of *eye-lids*, and are seldom even furnished with projections in place of eyebrows. In the moon-fish, (Tetraodon mola) however, the eye may be entirely covered with an eye-lid, perforated circularly. In the greater number of fishes, the skin passes directly over the eye without forming any fold, and in some cases it does not adhere very closely to the eye. Thus the common eel may be skinned without producing any hole in the situation of the eye, the skin only exhibits at that place a round transparent spot. In the trunk-fish, (Ostracion,) the conjunctiva, or external covering of the eye, is so similar to the rest of the skin, that we observe lines upon it, which form the same compartments as on the body of the fish. Some fishes may be considered as blind, as the Gastrobranchus cœcus, in consequence of the uniform opacity of the skin in passing over the eye.

The form of the eye in this tribe of animals is nearly that of a hemisphere, the plane part of which is directed forward, and the convex backward. In the Ray, the superior part is also flattened, so that the vertical diameter is to the transverse as 1 to 2. This flatness of the anterior part of the eye is compensated by the spherical form of the *crystalline lens.* This body is more dense in fishes than in land animals. Monro found the crystalline lens of an ox to be 1104, while that of a cod was 1165, water being reckoned at 1000. The crystalline lens projects through the pupil, and leaves scarce any space for the aqueous humour. The *vitreous humour* is proportionally small. The portion of the axis occupied by each of the three humours of the eye, in the herring, for instance, may be expressed in fractions as follows: aqueous humour $\frac{1}{7}$, crystalline lens $\frac{3}{7}$, and the vitreous humour $\frac{1}{7}$. The spherical form of the crystalline lens has been already stated; but the following Table, from the observations of Petit and Cuvier, will exhibit more clearly the proportion between the axis and the diameter in a few species.

The axis is to the diameter in the

Salmon as	9 to 10
Sword-fish	25 : 26
Shad	10 : 11
Pike	14 : 15
Barbel	11 : 12
Carp	14 : 15
Mackrel	12 : 13
Whiting	14 : 15
Shark	21 : 22
Ray	21 : 22
Herring	10 : 11
Tench	7 : 8
Eel	11 : 12
Conger	9 : 10

The *sclerotic coat* of the eye of fishes is more firm and dense than in the higher animals. It is here cartilaginous, semitransparent, and elastic, and sufficiently solid to preserve its form of itself. In the salmon it is of the thickness of a line posteriorly, and of an almost bony hardness before. This is frequently the case in other fishes, especially near its junction with the cornea, where it sometimes appears like an osseous ring. The outer layer of the *choroid coat* is either white, silvery, or gold-coloured, and is very thin and little vascular. The inner coat, to which the term *membrana Ruyschiana* has been applied, is in general black, and covered everywhere by mucous substance. In the ray, however, it is transparent. Between these two membranes of the choroid coat there is a body of a brilliant red colour. Its form is usually that of a thin cylinder, formed like a ring round the optic nerve; the ring, however, is not complete, a segment of a certain length being always wanting. Sometimes, as in the *Perca labrax*, it consists of two pieces, one on each side the optic nerve. It is considered by some as muscular, and enabling the eye to accommodate its figure to the distance of the objects; while others regard it as glandular, and destined to secrete some of the humours of the eye. This gland, we may add, does not exist in the *Chondropterygii*, as the rays and sharks.

The *iris* is in general distinguished by its golden and silvery brilliancy. This arises from its transparency, allowing the natural colour of the choroid coat to be discerned. The pupil is different in form in the different species, but in general it approaches to circular or oval; in some genera, as the salmon, it projects into an acute angle at the anterior part. In the *Gobitis anableps* of Linnæus, the cornea is divided into two portions, and there is a double pupil with a single lens. In the ray, the superior edge of its pupil is prolonged into several narrow stripes disposed in radii, gilded externally, and black internally. In their ordinary state they are folded between the superior edge of the pupil and the vitreous humours: but when we press the superior part of the eye with the finger, they unfold themselves, and cover the pupil like a window-blind. In the torpedo, the pupil can be completely closed by means of this veil. No other fishes possess any thing similar to this conformation, although in most osseous fishes, there is at each corner of the orbit a vertical veil which covers a small part of the eye.

In general, the eyes of fishes are placed in a conical cup, and repose on a mass of gelatinous matter contained in a loose cellular substance. This trembling elastic mass affords the eye a point of support in all its motions. In the *Chondropterygii*, however, as the rays and sharks, the eye is joined to the extremity of a cartilaginous stalk, which is itself articulated in the bottom of the orbit. In this manner the muscles act on a long lever, and have therefore great power in moving the eye.

The *optic nerves* arise under the cerebrum, and are very large. They are composed either of distinct filaments, or of a single flat band, which is sometimes folded longitudinally on itself, and contracted into the figure of a cord. They cross each other without being confounded, and we plainly see that the nerve of the left side proceeds to the right eye, and that of the right side to the left eye. This crossing is less apparent in the cartilaginous fishes, although in the ray the right nerve passes through an opening in the left. These nerves pass directly through the membranes of the eye by a round hole. Internally they form a tubercle, which is papillated in the ray, sharks, and carps. The radiating fibres which arise from the edges of these tubercles to form the retina, are very obvious. In other genera the retina is formed from the edges of two long white caudæ, in the same manner as it arises in birds from the single white line.

The eye is one of the most important organs which fishes are known to possess. It enables them to perceive the approach of their foes, and it is the principal instrument by which they obtain their food. The amateur in artificial fly-fishing often tempts the fish with one kind of fly, but in vain; and upon substituting another in its place of a different form or colour, he succeeds in the capture. These motions of the fish are all regulated by the eye; hence some fish will bite as readily at a bit of red cloth as at a piece of flesh.

As this organ exercises a very powerful influence on the habits of fishes, it should be carefully attended to by the systematic ichthyologist. The characters which are furnished by its form and position are not liable to variations, and they are sufficiently obvious. Those furnished by the colours of the different parts hold a secondary rank. They are not very liable to vary, but they experience great changes after death, and should be used with very great caution.

Hearing.

3. *Organs of hearing.* It was long known to naturalists, that fishes possessed some means of distinguishing the vibrations of sonorous bodies. Trouts and carp have been taught to come to a particular place of the pond for food upon a bell being rung; and a drum has sometimes been employed to drive fishes into a net. In general, however, it was supposed that the vibrations communicated to the water, became sensible to the fish, through the medium of the organs of touch.

The Abbé Nollet (in the *Hist. de l'Acad. R. des Sciences*, 1743, p. 26.) ascertained by conclusive experiments, that the human ear was susceptible to the impressions of sound, even when immersed in water. This discovery excited the attention of anatomists to the structure of the organs of hearing, and Camper, Geoffroi, and Vicq d'Azyr, succeeded in pointing out the nature of the different parts. Our illustrious countryman Dr Monro, in his work on the structure and physiology of fishes, contributed to enlarge our knowledge of the organs of hearing by numerous accurate dissections.

In the osseous fishes, no external ear has hitherto been detected, and the same remark is applicable to those cartilaginous fishes which have free branchiæ. But in the cartilaginous fishes with fixed branchiæ, small apertures have been discovered leading to auditory organs. These were first observed by Monro in the skate and the angel shark. In the former fish they occur in the back part of the occiput, near the joining of the head with the spine. They are two in number, not larger than to admit the head of a small pin; and in a large fish are found at the distance of an inch from each other.

In fishes that have free branchiæ, the internal organs of hearing are situated in the sides of the cavity of the cranium, and fixed there by a cellular tissue, consisting of vessels, and osseous or cartilaginous frœna. In the fishes with fixed branchiæ, those organs are inclosed in a particular cavity formed in the substance of the cranium. This cavity is situated on the side and posterior part of that which contains the brain, with which it does not communicate, except by the holes that afford passages for the nerves. The sac exhibits many differences as to size and form in the different species. Besides the ordinary viscid fluid, there are some small cretaceous bodies suspended by a beautiful plexus of nerves. These, in the osseous fishes, are three in number, and are hard and white like porcelain. In the cartilaginous fishes with free branchiæ, these bodies are in general fewer in number, and of a softer consistence, being seldom harder than moistened starch. It is supposed that these bodies assist in communicating to the nerves the vibrations produced in the water by sound. With the sac are connected three semicircular canals, filled with a viscid fluid similar to that in the large sac. The *auditory nerves* arise so near to the origin of the fifth pair, that they have been considered as the same. In the genus Raja these pass into the cavity of the ear by a particular foramen; in the osseous fishes, they are distributed directly into that organ.

As the ear of fishes is much less complicated in its structure than in the higher orders of animals, we may conclude that the sense of hearing is weak in proportion. Indeed the difficulty of detecting any natural movements of fishes, occasioned by sound, led the ancients to conclude that they did not enjoy this sense. We have, however, demonstrated its existence, but we are unable to ascertain the advantages which these animals derive from it, or the influence which it exerts on their habits and economy. In systematic ichthyology, the characters of the organs of hearing are too minute and difficult of detection, ever to be employed. They vary in different species, it is true, and may be resorted to in cases of difficulty; but for their investigation they require a dexterous hand and an experienced eye.

Tasting.

4. *Organs of Taste.* As the tongue of fishes (the organ in which the sense of taste resides in the higher orders of animals) is but imperfectly developed, naturalists are in general disposed to conclude, that the sense of taste can scarcely be said to belong to this class of beings. It presents no visible distinct papillæ, and its skin is analogous to the common integuments of the mouth. The nerves which supply it, are branches of the same nerves which proceed to the branchiæ. In the present state of our knowledge it is impossible for us to assign the precise influence which the sense of taste exercises on the economy of fishes. If noxious ingredients exist in the water, it appears probable, that some warning will be given the animal of their presence, either by the nerves of the mouth during the passage of the water to the gills, or by the latter organs. It does not appear that this sense is ever used in the discrimination of food, and does not furnish any characters, as such, to the systematic ichthyologist.

5. *Organs of Touch.* We have already observed that the skin of fishes is destitute of the corpus papillare, and hence anatomists have concluded, that they possess the sense of touch in a very limited degree. Besides, few nerves have hitherto been traced to the skin; and as its surface is in general coated with scales, it appears but ill adapted for receiving very delicate impressions. In some species, such as the common trout, (*Salmo fario,*) the sense of touch is well displayed, if, under a stone or bank, the hand be moved gently towards it, and its sides titillated. It will exhibit the pleasure it derives by leaning on the hand, and if the operation be performed with care, every part of the body may be gently stroked, and the fearless fish in part raised above the water.

From these observations on the organs of sensation, the reader will readily perceive that fishes hold a much lower place in the chain of being than quadrupeds or birds. The organs of smell and sight, appear to be more completely developed than those of hearing, taste, or touch, and therefore claim the attentive consideration of the student in his enquiries after a natural method in ichthyology.

Fishes possess no voice by which they can communicate their sensations to others. Some species utter sounds when raised above the water, by expelling the air through the gill opening when the flap is nearly closed.

Structure and Functions of Fishes.

While others, even under water, as the salmon, utter certain sounds while in the act of depositing their spawn; but for what purpose these sounds are uttered, or by what organs they are produced, we are still ignorant.

Sect. IV. *Organs of Motion.*

Organs of motion.

If we attend to the vast variety of forms, exhibited by different kinds of fish, we shall be disposed to conclude that *shape* exercises but little influence on their movements. While some are cylindrical and lengthened, others are nearly globular: some are depressed, while others are compressed. The general form, however, approaches to ovate, the body being thickest at the thorax, and tapering a little towards the head and tail.

The *fins* of fishes, correspond with the wings of birds, the former being calculated to give the motion to the body in the water, the latter in the air. These organs vary in number, size, situation, and structure, in different species.

The *number* of fins varies according to the genera, and even according to the species. It is difficult to fix on those fins which exercise the greatest influence on the habits of the animal, as there is not any one fin common to all fishes, although all fishes have at least one of these organs. The *size* of the fins is equally various in the different species, as it bears no constant proportion to the figure or magnitude of the fish, nor to its habits or instincts.

The *situation* of the fins furnishes the ichthyologist with some of the most obvious and useful characters. Those fins which are situated on the back are termed *dorsal*, and vary greatly in number and shape. The fin which surrounds the extremity of the tail, is termed the *caudal* fin, and is always placed perpendicularly. It is forked in some, even, or rounded in others. Between the caudal fin and the anus are situated the anal fins, which vary in number and shape according to the species. Between the anus and throat are placed the ventral fins. When they do exist, they never exceed two in number, and are parallel to each other. The *pectoral fins* are usually two in number, and are placed on each side, a short way behind the gill opening. By Linnæus and others, the ventral fins are considered as analogous to the feet of quadrupeds, and the characters furnished by their position are employed as the basis of his classification. Those fishes which are destitute of ventral fins, are termed, in his system, *apodal*; those which have the ventral fins placed nearer to the anterior extremity than the pectoral fins, are termed *jugular;* those having the ventral fins beneath the pectoral, he calls *thoracic*, and when the ventral fins are placed behind the pectoral fins they are termed *abdominal*. These distinctions are of great importance in an artificial system, and may be employed with success in the inferior divisions of a natural one.

The *structure* of the fins of fishes has long occupied the attention of naturalists. In general these organs consist of numerous jointed rays, which are subdivided at their extremities. These are covered on each side by the common integuments, which form in some instances soft fibres projecting beyond the rays. These fins, with articulated rays, were considered by the older ichthyologists as furnishing characters for arrangement of great importance. Fishes possessing these were termed *malacopterygii*. Besides these articulated rays, there exist in the fins of some fishes, one or more rays made up of a single bony piece, enveloped like the former by a common membrane. Some fishes have one or more fins consisting entirely of these bony rays. Fishes with such rays are termed *acanthopterygii*. In a few genera the posterior dorsal fin is destitute of rays, and has obtained the name of *pinna adiposa* or flesh-fin.

As these rays serve to support the fins, and are capable of approaching or separating like the sticks of a fan, we may conclude that they move upon some more solid body as a fulcrum. Accordingly we find in the sharks, for example, that the rays of the pectoral fins are connected by a cartilage to the spine. In the osseous fishes the pectoral fins are attached to an osseous girdle which surrounds the body behind the branchiæ, and which supports the posterior edge of their aperture. This osseous girdle is formed of one bone from each side, articulated at the posterior superior angle of the cranium, and descending under the neck, where it unites with the corresponding bone. Between the rays of the fin and this bone, which resembles the scapula, there is a range of small flat bones separated by cartilaginous intervals, which may be compared to the bones of the carpus. The rays of the ventral fins are articulated to bones which correspond to the pelvis in the higher classes of animals. The pelvis is never articulated with the spine, nor does it ever form an osseous girdle round the abdomen. In the jugular and thoracic fishes it is articulated to the base of the osseous girdle which supports the pectoral fins. In the abdominal fishes, the bones of the pelvis are never articulated to the osseous girdle, and are seldom connected with each other. They are preserved in their situation by means of certain ligaments. The rays of the caudal fin are articulated with the last of the caudal vertebræ, which is in general of a triangular form and flat. The rays of the dorsal fin are supported by little bones, which have the same direction as the spinous processes, and to which they are attached by ligaments.

As connected with the fins, we may here take notice of those organs which are termed cirri or tentacula, according as they are placed about the mouth, or on the upper part of the head. They are in general soft, but often contain one jointed ray. They do not differ in structure from the fins, and are so closely connected with them, that it is difficult to point out their use. It is not probable that they are organs of touch, but rather peculiar modifications of fins.

The muscles which move the fins, and all the other organs of the body, are of a paler colour than in the animals of a higher order. They are also more uniform in their substance, being in general destitute of tendinous fibres. In the greater number of fishes there are no muscles peculiar to the head. The sides are furnished with the most powerful ones, to execute the lateral movements of the animal. These muscles are disposed in layers or arches, with the convexity towards the head. The different muscles are strengthened by small detached spines, imbedded among the fibres of the muscle, and giving them additional strength. Between the layers there is in general a quantity of viscid albuminous matter interposed. After death this fluid speedily undergoes a change, and can seldom be observed in fishes which have been kept a few days. But in recent fish, when boiled, the albumen appears coagulated in the form of white curd between the layers of the lateral muscles.

The motions of a fish are performed by means of its fins. The caudal fin is the principal organ of progres-

Structure and Functions of Fishes.

sive motion. By means of its various flexures and extensions, it strikes the water in different directions, but all having a tendency to push the fish forward; the action resembling, in its manner and effects, the well known operation of the sailor termed *skulling*. The ventral and pectoral fins assist the fish in correcting the errors of its progressive motions, and in maintaining the body steady in its position. Borelli cut off with a pair of scissars both the pectoral and ventral fins of fishes, and found, in consequence, that all its motions were unsteady, that it reeled from right to left, and up and down, in a very irregular manner. The dorsal and anal fins serve to maintain the body in its vertical position. But from the circumstance of some of these fins being wanting, and others evidently too small to produce the desired effects, those fins which do exist appear to be capable of executing all the movements for which the others, when present, are designed.

The medium in which fishes reside prevent us from making any accurate observations on the velocity of heir motion. Mackrel, and some other marine fishes, will seize a bait moving at the rate of six or eight miles an hour; and some of the voracious sharks will keep up with a vessel in her voyage across the Atlantic. The darting of a salmon or trout in the water resembles the rapidity of an arrow, but such motion cannot be kept up for any length of time. This the angler is well aware of, who, with his hook fixed on very slender gut, will kill by fatigue the strongest salmon in the course of an hour or two, and a large trout in the course of two or three minutes. These facts seem to indicate, that however numerous and powerful the muscles of a fish may be, they are incapable of supporting a continued exertion.

Besides the action of swimming, fishes are likewise capable of *leaping*. They accomplish this by a violent effort of the caudal fin, or, according to some, by bending the body strongly, and afterwards unbending it with an elastic spring.

A few species are capable of sustaining themselves in the air for a short interval, and are termed *Flying-fish*. Such fish have the air bag, an organ to be noticed hereafter, of uncommonly large dimensions; hence the body has great buoyancy. The pectoral fins are likewise of an extraordinary size. Having by a leap raised themselves above the surface of the water, they continue in the air and move forwards, seldom farther than a hundred yards, by the action of their pectoral fins. The continuance of their flight is interrupted by the drying of the membrane of these fins, when they again fall into the water.

There is one species of fish (Perca scandens of *Lin. Trans.* vol. iii. p. 62.) which appears capable of *climbing*. By this motion, according to Lieutenant Daldorff of Tranquebar, it sometimes raises itself five feet above the surface of the water, mounting up the crevices of trees. The spines of its gill-cover retain it in its position; and when the body is bent to one side, the spines of the anal fin fix themselves in the bark; and when the body is then brought back to its ordinary shape, the head has reached a higher elevation. The spines of the expanded gill-covers again keep a firm hold, and a similar twisting of the body takes place in another direction. The spines of the dorsal fin contribute likewise to this extraordinary progression. The flying-fish leave the water to escape from other fishes which prey upon them; but the object to be gained by these movements of this fish has not been ascertained, nor has even a conjecture been offered on the subject.

The organs of motion, we have already hinted, are extensively employed by the systematic ichthyologist in the formation of his divisions. It does not appear, however, that naturalists have determined the exact value of the characters which they furnish, either for generic or specific distinctions. La Cepede, in some instances, has formed genera from a difference in the number of the dorsal fins; while into the genus Gadus, species with one, two, and even three fins, are admitted. As the number of the fins is invariably the same in the same species, and as these organs may be supposed to exercise considerable influence on the habits of fishes, the character thus exhibited may be safely employed in generic distinctions. The characters furnished by the structure of the fins have not been overlooked, especially the rays. The circumstance of being bony or jointed, is often noticed in specific distinctions, although well entitled to regulate divisions of a higher kind, as the character furnished is permanent. Those characters furnished by the fins, which are employed exclusively in the construction of species, are derived from their form, and the number of their rays. But as these characters are liable to vary in different individuals of the same species, they should be employed with great caution. In many fishes there are numerous rays on each side the different fins so concealed under the skin, that it is impossible to count them, while others do not reach the extremity of the organ. Hence the number of rays must vary with the mode of enumerating, and perhaps with the age of the animal. The extent of variation occasioned by the last cause has not been satisfactorily determined.

SECT. V. *Organ of Adhesion.*

Organ of adhesion.

THE organ here referred to, generally termed *sucker*, is only found on a few fishes. In some of these it is situated on the upper part of the head, while in others it is placed on the thorax. In the celebrated fish called the Remora, it is of an oval form, and consists of transverse rows of cartilaginous plates, connected by one edge to the surface of the head, and in the other edge free, and finely pectinated. A longitudinal partition divides the plates in the middle of the head. In the spaces between the plates, and on each side of the partition, a row of fleshy tubercles may be observed. In the cyclopteri this organ is of a circular form, and consists of numerous soft papillæ. It is situated on the thorax. Instead of a separate organ of adhesion, the ventral fins in the goby are united, and are capable of adhering to rocks and stones, while in the lampry the mouth contracts and acts as a sucker.

The existence of a sucker is equally common to some cartilaginous and osseous fishes. Its use to the fish is difficult to ascertain. When, by means of this organ, the fish attaches itself to the sides of other fishes, or to the bottom of ships, it is carried forward without any exertion of its own; and, during storms, adhesion to rocks by means of it, may save a weak fish from being tossed about by the fury of the waves; but there may perhaps be other purposes to which it is subservient, which still remain to be discovered.

The sucker furnishes to the ichthyologist characters for the discrimination of the species which are obvious and permanent; but these have seldom been described with accuracy or minuteness.

SECT. VI. *Organs of Respiration.*

Organs of respiration.

As the organs of respiration appear in fishes under a new form, very different from the lungs of the higher order of animals, they demand our attentive consideration. Many quadrupeds, birds, and reptiles, reside in water, but are obliged to come to the surface frequently in order to respire. But as fishes live immersed in the water, they are furnished with certain organs called Gills, instead of lungs, to enable them to exercise the functions of respiration in the fluid in which they reside. In many of the inferior animals, respiration is performed by the same apparatus; but as it appears in its most perfect form in fishes, its examination will be the more interesting.

These organs of respiration in fishes consist of four parts, a gill-lid, a gill-flap, the gill-opening, and the gills themselves. The two last are always present, but one, and sometimes both, of the two first are wanting. We propose to examine these parts in succession, beginning with those which are exterior.

Gill-lid.

1. *Gill-lid.* The gill-lid, or as it is also termed, *operculum*, is situated behind the eye on each side. It is scaly, membranaceous, or bony, and is articulated to the bones of the head. It consists sometimes of one piece, or of two or more, and is therefore termed monophyllous, diphyllous, or triphyllous. The surface in some is smooth, in others rough, or tuberculated, or striated, or spinous. Its use is to give support to the gill-flap, and act as a cover to the opening of the gills. It is absent in fishes which have fixed branchiæ, and in a few with free branchiæ. When it does exist, the characters which it exhibits in its structure are subject to little variation, and have been employed by La Cepede in the construction of his orders.

Gill-flap.

2. *Gill-flap.* This is the *membrana branchiostega* of Linnæus, and was considered by him as a true fin. It consists of a definite number of curved bones or cartilages, with a membrane. Its posterior edge is generally free, and its anterior edge or base is united with the gill-lid. It is capable of extension and contraction, and when at rest it is generally folded up under the gill-lid. It is wanting in the chondropterygii, and likewise in a few genera of osseous fishes. When present, it appears to assist the mouth in promoting the current of water through the gills, or perhaps forms a current over the gills when the mouth is occupied in seizing prey.

The gill-flap furnishes to the systematic ichthyologist some of his most useful characters. He seldom pays attention to its form, but its rays are eagerly counted, as he finds that they are not subject to vary. Species of the same genus have, in general, the same number of rays, and many of the Linnæan genera depend on this circumstance for their character. Artedi, on this subject, draws the following conclusion: "Quod numerus ossiculorum in membrana branchiostega primum et præcipuum characterem in distinguendis generibus piscium catheturorum et osteopterygiorum suppeditet." But in counting their number, care must be taken to examine the structure of the gill-lid at the same time, as the student sometimes enumerates among the rays of the gill-flap the posterior divisions of that organ, when present, and hence finds his observations at variance with the descriptions of authors.

Gill-opening.

3. *Gill-opening.* This division of the organs of respiration presents many remarkable differences. In the osseous fishes, and among the branchiostegi, this opening is a simple aperture behind the gills on each. It is sometimes round, or semi-lunar, and in relative position it differs according to the species or genera. In the cartilaginous fishes, the opening on each side is subdivided into as many apertures as there are gills, the gills in this tribe being fixed to the membranes which act as partitions in the opening. In such fishes, these openings are on the summit, at the sides, or underneath, according to the genera.

Gills.

4. *Gills.* In the fishes with gills or branchiæ, these organs are in general eight in number, four on each side. Each gill consists of three parts, a cartilaginous or bony support, and its convex and concave sides. The support of each gill consists of a crooked bone or cartilage, in general furnished with a joint. At its base, it is united with the bones of the tongue, and above with those of the head. At both extremities it is moveable, and throughout is flexible like a rib. Its position is nearly vertical. From its exterior or convex side, issue a multitude of fleshy leaves, or fringed vascular fibrils, resembling plumes, and closely connected at the base. These are of a red colour in almost all fishes in a healthy state. The internal or convex side of the support next the mouth exhibits many singular differences. It is always more or less furnished with tubercles. These in the genus Cyprinus are smooth—in the Cottus rough. They are lengthened into slender spines in the herring and smelt, but in the former these are serrated, while in the latter they are smooth. This concave part of the gill is of a white colour, and forms a striking contrast with the colour of the convex side.

In some osseous fishes, the number of gills exceeds four on each. In the herring, for example, there is a small imperfect gill on each side attached to the inner side of the gill-lid, on which all its motions depend. It has no bony arch nor concave side. At the entrance to the gullet, there is a cartilage on each side, studded with tubercles, resembling in appearance the concave side of the last gill. In the *plaise*, a similar gill may be observed on the inside of the gill-lid, but no distinct appearance of a sixth gill at the entrance to the œsophagus.

In the chondropterygii, the gills are far from being so perfect. They are fixed to partitions which serve the purposes of the bony arches in the osseous fishes. These partitions extend from the mouth to the gill-opening, and vary in number according to the genera. They are destitute of the inner or concave white side, but the fleshy leaflets are of the same structure with those on the convex part of the gills in osseous fishes.

We are indebted to that acute anatomist, Sir Everard Home, for some important observations on the respiratory organs of the lamprey and myxine, the apodal chonropterygious fishes, and the least perfect in the system. "In the lamprey, (he says), the organs of respiration have seven external openings on each side of the animal; these lead into the same number of separate oval bags, placed horizontally, the inner membrane of which is constructed like that of the gills in fishes. There is an equal number of internal openings leading into a tube, the lower end of which is closed, and the upper terminates by a fringed edge in the œsophagus. These bags are contained in separate cavities, and enclosed in a thorax resembling that of land animals, only composed of cartilages instead of ribs, and the pericardium, which is also cartilaginous, is fitted to its lower extremity like a diaphragm." In the myxine,

Structure and Functions of Fishes.

the external openings are two in number, but there are six lateral bags on each side, placed perpendicularly, to which there are six tubes from each of the openings, and close to the left external opening, there is one which passes directly into the œsophagus. (*Phil. Trans.* 1815, Part II. p. 256.)

The characters furnished by the gills are of the first importance in arranging the species. They are easily examined, and the distinctions are obvious. But by some strange conceit, ichthyologists seldom look into the gills, or point out to us the peculiarities which they exhibit. Indeed the characters furnished by the organs of respiration should be regarded as occupying the highest rank. Without the aid of any other characters, fishes might be classified with ease, and even species might be determined with certainty.

SECT. VII. *Organs of Circulation.*

Organs of circulation.

THE organs of circulation are not so obvious as those which we have been considering, and are seldom attended to by the mere ichthyologist. Without entering into the minute details of comparative anatomy, we trust the following observations may not prove uninteresting to the general reader. The *heart* of fishes is situated in the forepart of the body, in a cavity between the gills and a little behind. The pericardium or membrane which lines this cavity, is similar to the covering of the cavity of the abdomen, and like it, is often spotted or silvery. In the skate, Dr Monro found the bottom of the pericardium lengthened into the shape of a funnel, which divides into two branches. These are tied closely to the lower part of the œsophagus, and open into the cavity of the abdomen. Into this cavity there is secreted a liquor, afterwards to be taken notice of. The heart itself is small in proportion to the body of the animal, and varies greatly in figure in the different species. It is quadrilateral in some, and semicircular in others. It consists, as we have already mentioned, of a single auricle and a single ventricle, corresponding to the right side of the heart of warm-blooded animals. The auricle is in general larger than the ventricle, and of a thinner texture in its coats. It receives the blood from the body, and transmits it to the ventricle. This last division of the heart has walls of considerable thickness. It sends forth an artery, which, at its separation from the heart, forms a bulb varying in shape according to the species. This artery subdivides and proceeds directly to the gills, over whose leaves it is spread in the most minute ramifications.

The blood, in passing through the gills of fishes, undergoes similar changes as the blood of quadrupeds in passing through their lungs. It is likewise now well established, that the atmospheric air contained in the water furnishes to the blood those materials which are necessary for its purification, and a continuance of the life of the animal.

The water for this purpose is taken in at the mouth, and sent to the gills, where, after being in a great measure deprived of the oxygen of its atmospheric air, the water is ejected through the gill opening.

"In the lamprey," according to Home, "the water is received by the lateral openings of the animal into the bags which perform the office of gills, and passes out by the same opening; the form of the cavities being fitted to allow the water to go in at one side, pass round the projecting parts, and out at the other. A part of the water escapes into the middle tube, and from thence either passes into the other bags, or out at the upper end into the œsophagus. There is a common opinion that the water is thrown out of the nostril: this, however, is unfounded, as the nostril has no communication with the mouth."—"In the myxine, the elasticity of the two tubes, and the bags into which they open, admits of the water being received; and the pressure produced by the action of the external muscles forces it into the œsophagus, from whence it is thrown out by the opening at the lower end of that tube."

If the ejection of the water from the gills of a fish be prevented, by the gill cover being tied down with a string, it soon expires in convulsions. Similar fatal consequences follow, when fish are placed in water previously deprived of its atmospheric air by boiling or freezing: and when fish are kept in a small pond, whose surface is frozen over, and where the water in that case cannot obtain a fresh supply of air, they speedily perish. If a small opening be made in the ice, before it be too late, the fishes will come near it for a fresh supply. In this manner, fishes are frequently taken during winter in ponds and lakes.

The extent of surface presented by the gills of a fish, to enable the blood to come in contact with the air in the water, is much greater than one would, without attentive consideration, be led to suppose. Dr Monro calculated, that the whole gills of a large skate presented a surface equal to 2250 square inches, or equal to the whole external surface of the human body.

The process of respiration for the supply of the gills is carried on even during sleep. The number of respirations in a minute is seldom above thirty, or below twenty. In the same individual it is liable to considerable variation, depending on the will of the animal.

The blood, after being renovated in the gills, is reabsorbed by a multitude of minute vessels, which unite together; but, instead of returning the blood to the heart again, to be afterwards distributed through the body, this aorta exercises that function, and descends along the inferior side of the spine, in a canal fitted for its reception, giving off arteries, during its course, to the adjacent parts. The blood is absorbed again by veins, which have extremely thin coats. These are much larger in their course than in their termination; and besides form, in different parts of their course, considerable receptacles for blood.

Any injury received by the gills of fishes is attended with much pain, and a considerable effusion of blood. Some fishermen seem to be well aware of this last circumstance, and cut the gills with a knife as soon as the fish is taken. A copious bleeding takes place; and they find that a fish so killed will keep much longer in a fresh state, than one on whom this operation of bleeding has not been performed.

SECT. VIII. *Organs of Nourishment.*

Organs of nourishment.

IN attending to the organs of nutrition, it will be necessary to consider the structure of the mouth, and afterwards the gullet, stomach, and intestines.

Mouth.

The *mouth* of fishes exhibits many remarkable differences, according to the species, in regard to position, figure, and size. In general, it is situated at the extremity of the head, and is then said to be terminal. In some species, and even genera, it is placed beneath a snout, or on the under side of the head. Wherever situated, it is always transverse with respect to the body, unless in the genus Pleuronectes, in which it occupies an oblique position. When the mouth is opened, it is in general of an oblong or oval shape. In some fishes, its capacity is less than the size of the head; but, in general, it is capable of opening to a great width, sometimes superior to the thickness of the body.

Lips.

The *lips* of fishes are seldom regularly formed. In a few species, however, these surround the mouth, and are of a firm, fleshy consistence. In other instances, the lips are of an osseous texture, divided into plates which fold over one another. Such kind of lips give to the mouth increased dimensions, as they are capable of being exserted or folded up at the pleasure of the animal.

Jaws.

The *jaws* are moveable, and both are attached to the bones of the palate. They are seldom equal, the one exceeding the other in length. They furnish, by their position and mode of union, many important characters in the classification of fishes. These characters have been lately investigated by Cuvier with his usual success; and he is of opinion, that the maxillary and intermaxillary bones will furnish characters not for genera merely, but likewise for orders.

Teeth.

The *teeth* of fishes exhibit remarkable differences, with regard to number, situation, and structure. In the higher orders of animals, the number of teeth in the mouth is almost always constant in the same genera and species. But among fish, the teeth are often so numerous that it is difficult to count them, especially as they occupy so many different positions. The jaws are not exclusively employed to support these organs, as in quadrupeds; the tongue, the palate, the throat, being often furnished with them. In the saw-fish, the teeth are inserted on each side of its flattened and projecting snout. In the genus Sparus, the front teeth resemble those of the human species. They are provided with fangs, which are contained in alveoli. In many fishes, the teeth are formed of processes of the jaw bones covered with enamel. Those of the shark tribe adhere merely to the gums, or at least to a firm cartilaginous substance which covers the jaw. They are not formed, as in the mammalia, by the addition of new layers, one within the other, but apparently in a manner resembling the formation of bone. They are at first soft and cartilaginous, and pass, by successive gradations, into a state of hardness and density not inferior to that of ivory. In the skate, the teeth consist of an assemblage of tubes, covered externally by enamel, and connected to the jaw by a softer substance, which probably sends processes or vessels into those bony tubes.

The teeth of fishes are in general bent inwards, to enable them to retain their prey. As few fishes masticate, they have seldom any teeth which resemble grinders, although those which live on the harder shell-fish have teeth fitted for triturating these.

In the classification of fishes, the teeth furnish several important characters, which are little liable to variation. In the genus Squalus, in particular, the teeth exhibit many remarkable differences in form, sufficient, in the absence of other characters, for the discrimination of the species.

Gullet.

The *gullet* or œsophagus, on account of the absence of a neck, is in fishes remarkably short. In some, indeed, the stomach seems to open directly into the mouth. Where it exists, it exhibits few peculiarities of structure. In some of the branchiostegi it is beset with tufts of hair resembling a fine net-work. It is in general capable of great dilation, and when the stomach is unable to hold the whole of the prey which has been seized, a part remains in the gullet until the inferior portion gives way.

Stomach.

The *stomach* of fishes is in general thin and membranaceous, differing little in its structure and appearance from the gullet. It frequently contains the remains of crustaceous animals, still retaining their form, but greatly altered in consistency. Hence naturalists have concluded, that the food is reduced by solution, and not by trituration. But in some fishes, particularly those which subsist principally on shell-fish, the stomach has thick muscular coats. Its shape is considerably different in the different species, but the characters furnished by this organ are seldom regarded.

Intestines.

The *intestines* exhibit many remarkable peculiarities. Sometimes they proceed directly from the stomach to the anus in nearly a straight line. In other instances, they form in their course one or more flexures. In some instances, the gut is widest towards the stomach, and gradually becomes smaller as it approaches the anus, while in others the reverse of this is the case. It is furnished internally in some species with spiral valves, in others with lozen-shaped hollows, while in a few it has numerous fringed laminæ. Between the great and small intestines, in the chondropterygii, there is a kind of cœcum or appendix vermiformis; but in osseous fishes, there is no appearance of any such organ. In the last division, however, there are bodies which have been termed *Appendices*, or Intestinula-cœca. These are situated at the origin of the gut, in a double or single row. They vary in number, shape, or size, according to the species; but continue the same in all the individuals of the same species. In place of these in the chondropterygii, there is a glandular body, which has been compared to the pancreas of warm-blooded animals. The character for the discrimination of the species furnished by the appendages is of importance, as being easily investigated and permanent.

These intestines, and the rest of the viscera situated in the cavity of the abdomen, are contained in a membranaceous sac or peritonæum. This is silvery in some fishes, black or spotted in others. We are informed by Willoughby, that this sac opens externally near the anus by means of two small holes. These openings were afterwards examined by Monro, who found in each of these passages a semilunar membrane or valve, so placed as to allow liquors to get out from the abdomen readily, but to resist somewhat their entry into it.

The anus in fishes, occupies many different positions according to the species. This circumstance was seized upon by Scopoli, in the system which we have noticed above, and was raised to the dignity of a primary character in his system. This orifice is not merely the opening whence issue the fæces, but in general the spawn also.

Sect. IX. *Organs of Absorption.*

Organs of absorption.

The vessels of the absorbent system of fishes are analogous to those of quadrupeds. They are, however, destitute of valves, unless at their termination in the red veins, and do not appear to possess conglobate glands. Dr Monro, to whom we are indebted for the first illustration of this class of vessels, gives the following view of their arrangement in the cod and the salmon. " The chief branches," he says, " of the lacteal vessels of the great and small intestines, and which are smaller in proportion to the blood vessels than in the nantes pinnati of Linnæus, run upwards in the mesentery, almost parallel to each other, and near the mesenteric arteries. In their whole course, they communicate by a vast number of small transverse canals. At the top of the abdomen near the gall bladder, the lacteals of the stomach, and lymphatics of the spleen, liver, and intestinula cœca are added. The chyle, mixed with the lymph of the assistant chylopoietic viscera, passes upwards and towards the right side into a large receptacle contiguous to the gall bladder, and between it and the right side and back part of the lower end of the œsophagus. From the receptacle of the chyle, large canals pass upwards to the right and left, receiving in this course the lymph from the organs of urine and generation. Those on the left side are chiefly behind the œsophagus.

The chyle, mixed with the abdominal lymph, having ascended above the bones, which resemble our clavicles, is poured into large cellular receptacles, situated chiefly between the clavicles and the undermost of the gills, and which also receive the lymph from all the other parts of the body.

Four lymphatic vessels, which terminate in these receptacles, and which have their extremities contracted by a doubling of their internal membranes, chiefly merit attention. The first conveys the lymph from the middle of the belly, from the ventral and pectoral fins, and from the heart. The second runs up the side of the fish, parallel to the great mucous duct, and brings the lymph from the principal muscles of the tail and body. The third is deep seated, and conveys the lymph from the spine, spinal marrow, and upper part of the head. The fourth lymphatic vessel, or rather plexus of vessels, brings the lymph from the brain and organs of the senses, and from the mouth, jaws, and gills.

These receptacles may therefore be called the common receptacles of the chyle and lymph. The right receptacle communicates freely with the left by large canals, which pass chiefly behind the heart and œsophagus.

From each of these receptacles in the salmon, a canal runs downwards and inwards, and opens into the upper end of its corresponding vena cava inferior, contiguous to, and on the fore and outer side of the internal jugular vein. The termination of these canals are contracted, and their internal membranes are doubled, so as to serve the purpose of valves, in preventing the passage of the blood from the venæ cavæ into the receptacles. In the cod kind, the receptacles are proportionally larger than in the salmon; and, besides transmitting the muscles of the gills, and their several nerves, contain the upper cornua of the air bladder." (Monro, *Struct. and Phys. of Fishes*, p. 31.)

The termination of the lymphatic veins in the skin, may be readily ascertained in this class. Coloured liquors injected into them, are discharged by numerous pores, chiefly situated on the upper parts of the body. These orifices are placed at regular intervals. As Dr Monro did not observe any appearance of extravasation in the cellular substance, he considered that these orifices were the natural beginnings of the lymphatic veins.

Sect. X. *Organs of Secretion.*

Organs of secretion.

In considering the organs of this class, we propose to examine the structure of the liver, pancreas, kidneys, air, and mucous ducts.

Liver.

1. *Liver.* This organ in fishes, is remarkable on account of its size in proportion to the rest of the body. It commonly lies almost wholly on the left side. Its colour exhibits various shades of brown frequently mixed with yellow. It is entire in some fishes, as the lamprey, flounder, and salmon; or divided into two or more lobes, as in the perch and carp. These varieties of form are constant in all the individuals of the same species, but frequently differ somewhat in the species of the same genus.

The *gall bladder* is present in the greater number of fishes; but in a few species, as the lamprey, its presence has not been detected. The *bile* varies greatly in colour according to the species. In the thornback and salmon it is yellowish white, and, when evaporated, leaves a matter which has a very sweet and slightly acrid taste, containing no resin. The bile of the carp and eel is very green and very bitter, contains little or no albumen, but yields soda, resin, and a sweet acrid matter similar to that which may be obtained from salmon bile. The biliary ducts open separately into the intestine.

The liver appears to be the only organ of the body of fishes which contains oil in abundance, or is sought after on that account. This oil is lodged in cells, and cannot be completely obtained by the boiling of the liver. To accomplish the extraction of the whole oil, fishermen in general allow the livers to putrefy a little, and in this manner the cells are ruptured, and a greater quantity of oil obtained. But gelatinous matter and bile are likewise among the products, and as these afterwards putrefy, they communicate a fœtid smell to the oil. This disagreeable smell is common to all kinds of fish oil thus prepared; but it may be removed by various processes. Perhaps the best are those which were communicated to the Society for the encouragement of arts, manufactures, and commerce in the year 1761, and published in the twentieth volume of their Transactions, to which we refer the reader. The liver of the cod, cut into small pieces, boiled in the stomach of the same animal, and eaten with vinegar and pepper, is a favourite dish in the northern islands of Scotland.

Pancreas.

2 *Pancreas.* In the chondropterygii, there is a pancreas resembling that in the higher classes of animals, of an irregular form, and placed at the origin of the intestines. The substance appears compact, but gelatinous when cut. In the osseous fishes, the intestinula cœca already described, appear to serve instead of a pancreas. They send two large canals into the intestines; and when these are wanting, as is the case in the carp, the walls of the intestines discharge abundance of humour from glands placed upon their inner surface. In the sturgeon, an organ is found, in its internal structure similar to these intestinula; but in its outward form resembling the pancreas of the skate. It is inclosed in a muscle, evidently intended to express its contents. It opens into the intestine by three large orifices, and has internally a singular reticular appearance, as exhibited by Monro in the work on fishes so often referred to, page 84. tab. ix.

Spleen.

3. *Spleen.* This organ varies greatly in its form and position in the animals of this class. In some it is nearly triangular, while in others it approaches to a spherical figure. It is in general entire; in some instances, however, it is divided into lobes, which adhere by very slender filaments. In the sturgeon, these lobes are seven in number. It is placed in some species on the stomach, or to the first part of the intestines; in others between the stomach and liver; and in a great number it is under the air bag, and above the other bowels. It is always of a darker colour than the liver.

Kidneys.

4. *Kidneys.* It was the opinion of Rondeletius and others, that fishes were destitute of kidneys and the

bladder of urine; but the observations of Willoughby and others have demonstrated their existence. The kidneys of fishes are uniform in their substance, and of a reddish brown colour. They are in general long and narrow, and apparently united into one mass. The peritoneum covers their under surface, and they are placed longitudinally under the spine. The ureters begin by numerous roots, and run along the under surface of the kidney. They terminate either in a vesica urinaria, or a cloaca; or unite together to form a dilation, which supplies the place of a bladder of urine.

In the chondropterygii, the ureters terminate in the cloaca, but in the other cartilaginous fishes the bladder of urine is present, although very small and thin in its coats. The urethra in most fishes is short, and commonly opens behind the anus by an orifice which also gives issue to the sexual evacuations. Renal glands are wanting in this class.

Air-bag.

5. *Air-bag.* This organ is called by some the swimming bladder, by others the air bladder. It is the vesica natatoria of Willoughby, and the vesica aerea of Artedi. In this country it is called the *sound.* When present, it is situated in the anterior part of the abdominal cavity, and adheres to the spine. It is wanting in the chondropterygii, and even in some of the osseous fishes, as the flounder and mackrel.

It is very different in shape according to the species. In the herring and some other fishes it is oblong and pointed at both ends. In the salmon it is obtuse at both ends. In the burbot it is obtuse in the lower end, and bifid at its superior extremity. In the carp it is divided transversely, and in the silurus longitudinally, into two lobes.

In general there is a duct (*ductus pneumaticus*), by means of which this air bag communicates with the œsophagus, or the stomach. In the sturgeon there is a round hole, nearly one inch in diameter, in the upper and back part of the stomach, communicating with the air bag. The hole is surrounded by thin muscular fibres placed between the membranes of the stomach and air bag, which decussate at opposite sides of the hole. These are considered by Monro as having the effect of a sphincter muscle. In the salmon, the last quoted author found a hole so large as to admit readily the largest sized goose quill, leading directly through the coats of the œsophagus into the air bag. The œsophagus in this fish has a thick muscular coat, but the fibres of that coat do not seem to form a distinct sphincter around the hole. In other fishes the duct of communication is of considerable length. In the common herring the under part of the stomach has the shape of a funnel; and from the bottom of the funnel a small duct is produced, which runs between the two milts, or the two roes, to its termination in the middle of the air bag. In some fishes, as the cod and haddock, Monro could not perceive any ductus pneumaticus, or opening into any of the abdominal viscera. The air bag was not enlarged by blowing into the alimentary canal, nor could he empty the air bag without bursting it.

In the air bag of the cod and haddock, the same acute observer examined the red coloured organ noticed by Willoughby, and considered by him as a muscle, the surface of which is very extensive, as it is composed of a vast number of leaves or membranes doubled. In those fishes, however, in which the air bag communicates with the alimentary canal, this red body is either very small and simple in its structure, as in the conger eel, or entirely wanting, as in the sturgeon, salmon, herring, and carp.

Naturalists, in general, are disposed to regard the air bag as accessory to the organs of motion. Having observed that flat fish, which reside always at the bottom, are in general destitute of this organ, they have assigned to it the office of accommodating the specific gravity of fishes to the density of the surrounding element, and thus enabling them to suspend themselves at any depth. A very simple experiment has likewise countenanced the opinion. When the air bag of a fish is punctured, the animal immediately falls to the bottom, nor is it able, by any exertion of its fins, to elevate itself again. When in a sound state, the external skin of the air bag (regarded as possessing strong muscular power) is supposed capable of contraction, so as to condense the air, and enable the animal to sink, or of extension, so as to allow the air to expand, and aid the animal in rising in the water.

The air bag of some fishes soon loses its muscular power, in consequence of the air being expanded by the action of the sun, when the fish has remained too long at the surface. In this situation the fish continues at the surface. When some fish are suddenly brought up from deep water, the diminished pressure occasions the expansion of the air contained in the bag. The organ sometimes bursts in such cases, and the contents, rushing into the abdomen, push the gullet sometimes out of the mouth of the fish. We have witnessed this effect produced in the cod fish.

The above theory fails in explaining all the phenomena. The eel, which resides always at the bottom, is yet possessed of an air bag; while the sharks, which roam about in all depths, and the mackrel, which pursues its prey at the surface, are destitute of this reputed organ of equilibrium.

Various opinions have been advanced with regard to the manner in which this air bag is filled. By some it has been supposed, that a portion of the air, which fishes are capable of abstracting from the water, is transmitted through the gullet and stomach into the air bag when necessary, and expelled and renewed at the pleasure of the animal. Needham long ago considered that the air, or, as he termed it, a vaporous exhalation contained in the air bag, was generated in the blood, secreted into this organ, to be afterwards thrown into the stomach or intestines, to promote the digestion of the food.

The nature of the air contained in the air-bag, was never investigated until pneumatic chemistry had opened up new fields of discovery. In 1774, Dr Priestley turned his attention for a short time to the subject; and in the air-bag of the roach he found azote in one instance unmixed, and in another in company with oxygen. Fourcroy afterwards examined the gaseous contents of the air-bag of the carp, and found them to consist of almost pure azote.

The most accurate and extended experiments on this subject are those of M. Biot, published in the *Mem. d'Arcueil,* i. 252. and ii. 8. He found the proportion between the oxygen and the azote (for he was unable to detect the presence of hydrogen, or any sensible quantity of carbonic acid) to vary according to the species, as may be seen in the following table.

Names of the Fish.	Proportion of Oxygen.
Mugil cephalus	quantity insensible.
Ditto	ditto.
Murænophis helena	very little.
Sparus annularis, female	0.09
Ditto, male	0.08

Names of the Fish.	Proportion of Oxygen.
Sparus sargus, female	0.09
Ditto, male	0.20
Holocentrus marinus	0.12
Labrus turdus	0.16
Sparus melanurus	0.20
Labrus turdus var.	0.24
Sciæna nigra, female	0.27
——— male	0.25
Labrus turdus, female	0.24
——— male	0.28
Sparus dentex, female	0.40
Sphyræna spet (Esox sphyræna, Lin.)	0.44
Sparus argenteus	0.50
Holocentrus gigas	0.69
Gadus merluccius	0.79
Trigla lyra	0.87

The depth at which the fishes had been caught increases from the beginning to the end of the table, and the proportion of oxygen observes the same rule. This last circumstance induced Biot and his friend De Laroche to endeavour to ascertain the proportion of oxygen contained in sea water at different depths. They were unable to perceive any difference. M. Configliachi has more lately repeated these experiments, and found that the proportion of oxygen in sea water bore no relation to the depth from which the water had been obtained.

These experiments lead to the conclusion, that the air contained in this sac is a secretion of the organ; that in fishes which live near the surface azote is secreted; but in fishes which live at great depths, the quantity of oxygen is proportionally increased. The purposes accomplished by this arrangement have never been explained in a satisfactory manner. The red organ which we have already taken notice of as existing in some fishes, is now generally considered as the part which separates this air from the blood. But as this organ is not always present when there is an air-bag, we are still left in doubt on the subject.

To the systematic ichthyologist, the characters furnished by the air-bag are of considerable importance, although seldom sufficiently attended to. They are easily traced, and they are not subject to variation.

To the economist, the air-bag or sound is considered as an article of value. This organ in the cod or ling, when salted, forms a nourishing and palatable article of food, held in high estimation in the northern islands of this country. But it is chiefly in the manufacture of the substance called ISINGLASS that the sounds of fishes are extensively employed. The sounds of various kinds of sturgeon are chiefly made use of for this purpose. The external membrane is removed, and the remaining part is cut lengthwise, and formed into rolls, and then dried in the open air. The sounds of cod and ling are frequently employed as a substitute for those of the sturgeon. They require some dexterity to separate them from the back-bone. But when the membranes are well scraped on both sides, steeped for a few minutes in lime water to absorb the oil, and then washed in clean water and dried, they form an isinglass of considerable value.

Isinglass consists almost entirely of gelatine, and is used either as food, or for the purpose of fining liquors. 500 grains of it yielded to Hatchet by incineration 1.5 grains of phosphat of soda, mixed with a little phosphat of lime. An inferior kind is manufactured from the bones, fins, and useless parts of fishes. These materials are boiled in water, the fluid skimmed and filtered, and afterwards concentrated, until it readily gelatinizes on cooling. This kind is much used in various manufactures, and might be obtained in considerable quantity at all the fishing stations in this country where the materials abound, but which are at present left as a nuisance on the adjoining beach.

Mucous ducts.

6. MUCOUS DUCTS. The surface of the skin of fishes is almost always covered with a slimy fluid, to protect them from the penetrating influence of the surrounding element. This mucus is poured out from small pores, situated under the scales in every part of the body of some fishes, while in others these excretory ducts are arranged in a determinate order. These ducts were first observed and described by Steno, in his works, " *De Musculis et Glandulis*, p. 42. and *Elementorum Myologiæ Specimen*, 1669, 8vo. p. 72. The subject was afterwards investigated by Perrault, Lorenzini, and Revinus, and more recently by Monro. To this last author we are indebted for many excellent observations and sketches. " In the skate," (he says, *Struct. and Phys.* p. 21.) " numerous orifices, placed pretty regularly over the surface, have been observed by Steno to discharge this slimy matter. With respect to these last, I have remarked some memorable circumstances. First, I have discovered one very elegant serpentine canal between the skin and muscles, at the sides of the five apertures into the gills. Farther forwards it surrounds the nostrils; then it passes from the under to the upper part of the upper jaw, where it runs backwards as far as the eyes. From the principal part of this duct, in the under side or belly of the fish, there are not above six or eight outlets; but from the upper part near the eyes there are upwards of thirty small ducts sent off, which open upon the surface of the skin. The liquor discharged from these has nearly the same degree of viscidity as the synovia in man. But besides the very picturesque duct I have been describing, I have remarked on each side of the fish, a little farther forwards than the five breathing holes, a central part from which a prodigious number of ducts issues, to terminate on almost the whole surface of the skin, excepting only the snout or upper jaw. At these centres all the ducts are shut; and in their course they have no communication with each other. In these two central parts, or on the beginning of the mucous ducts, a pair of nerves nearly as large as the optic, terminate; and, which is a curious circumstance with respect to them, they are white and opake in their course, between the brain and their ducts; but when they divide, they become suddenly so pellucid, that it is impossible to trace them farther, or to distinguish them from the coats of the ducts."

Lateral line.

In the osseous fishes, the openings of the mucous ducts are chiefly observable in the fore part of the head, and in the *lateral line*. This line extends from the head to the tail, along each side of the fish, and exhibits several striking peculiarities. It is not observable in the lampry; in general it is single, but in the sandeel it has the appearance of being double. It is usually of a different colour from that of the sides, and varies according to the species in position and direction. After death it sometimes disappears, and hence some difficulties have arisen with regard to the discriminating marks which it furnishes.

The mucus which is poured out upon the skin by these ducts, in some cases appears to be the liquid known by chemists under that name, while in other instances it appears to be of the nature of albumen. Chemists, however, have not turned their attention to the subject.

Besides this liquid, secreted on the external surface of the body, many physiologists have detected liquors in the cavity of the brain, the pericardium, and the abdomen, which we may take notice of in this place. Dr Monro found the liquor surrounding the brain of a skate to be of a saltish taste; and his friend Dr Rutherford found that it contained one sixty-fifth part of its weight of sea salt dissolved in it. The liquor in the cavity of the abdomen contained only one seventy-eighth part.

SECT. XI. *Organs of Reproduction.*

Organs of reproduction.

The reproduction of fishes is a subject involved in great obscurity. The element in which they reside conceals from us the actions which they perform, and hence we are unable to point out with certainty the uses of the different organs, or the functions which they exercise. Even in the days of Aristotle the difference in the mode of reproduction between the cartilaginous and the osseous fishes had been observed; and although many accurate observations have been made by modern zootomists, much still remains to be done both in the field of observation and dissection.

In the general view which we propose to give of this subject, fishes may be divided into two classes, distinguished by their reproductive organs. Thus, some have the sexes distinct, while in others they are united. Those with the sexes distinct may be subdivided into the oviparous and the false viviparous, or ovoviviparous.

Sexes distinct. Oviparous.

1. *Oviparous fishes, with the sexes distinct.* The fishes included under this division are by far the most numerous. They have all free branchiæ. Some of them possess a cartilaginous skeleton, while others belong to the division termed osseous. In all, the egg is impregnated externally, and arrives at maturity without the aid of the mother.

In the *males* of this division, the testes, known by the name of *milts*, are two in number, of a white colour, and lengthened form. The surface is usually irregularly tuberculated. They are situated on each side of the abdomen, and consist of glandulous sacs destined for the preparation of the impregnating fluid. Through the middle of each milt there passes a ductus deferens, uniting with each other at the posterior part of the abdomen, and forming a kind of vesicula seminalis. The external opening for the issue of the semen is in some in the cloaca, while in others there is a small orifice situated behind the anus, which gives vent to the sexual evacuations.

In some of the oviparous abdominal fishes, there are two cartilaginous fins situated between the ventral fins, and supposed by La Cepede to be the external openings of the sexual organs. They are termed by him *Appendices genitals.*

We possess few accurate experiments on the chemical composition of the seminal fluid of fishes. Fourcroy published in the *Annales de Chim.* vol. lxiv. p. 3. some experiments on the milt of the carp. It was neither acid nor alkaline. It appears to consist of albumen, gelatine, phosphorus, phosphat of lime, phosphat of magnesia, and muriat of ammonia. More recently, Dr John subjected the milt of a tench to a chemical analysis, and obtained the following ingredients: water, insoluble albumen, gelatine, phosphat of ammonia, phosphat of lime, phosphat of magnesia, and alkaline phosphat. He could not detect the presence of any phosphorus, which had been given as a constituent by Fourcroy and Vauquelin. In all these examples, however, the seminal fluid was mixed with the substance of the testes.

In the *females* of this division, the ovary, usually termed the *roe*, is double in the greater number of fishes, but in a few it appears to be single. It occupies nearly the same position as the milt in the males. It consists of a thin delicate membrane inclosing the ova. These are generally disposed in transverse layers, connected by means of blood vessels. There is no distinct oviduct. The external openings are similar to those in the male.

Previous to the deposition or ejection of the roe or eggs by the female, a union has been formed with a male. But this connection is merely temporary, and is dissolved immediately after the impregnation of the egg has taken place. In the Cyclopterus lumpus, however, it is stated that this connection is of longer duration, that they continue to watch over the eggs with tender solicitude, and defend them from the rapacity of other fishes. The pleasure derived from the belief in this singular example of parental care, is in a great measure destroyed by the hint which has been thrown out, that they defend the eggs from the attack of other fishes, that they may appropriate them as a feast to themselves.

The ova are first deposited by the female, and then the male pours upon them the impregnating semen. In many instances, they form a hole in the sand, by their mutual assistance, and place therein the roe; in other instances, the roe is deposited in the crevices of rocks, or on sea weeds or aquatic plants. But it would be endless to detail the various ways (even were we better acquainted with them than we profess to be) in which fishes perform this curious function of their nature.

The eggs of fishes are very various with respect to colour, but agree in being of a spherical form. The integument is more or less firm according to the species. The yolk, instead of occupying the centre, as in the eggs of birds, is placed laterally, and is surrounded by the glaire or albuminous matter. Between the yolk and the glaire, is situated the germ or embyro. The germ becomes ready for exclusion at very different periods, according to the species. Thus the egg of the carp is said to be perfected in the course of three weeks, while that of the salmon requires as many months. But in the eggs of the same species, a great deal depends on the temperature to which they are exposed. In the same pond, those eggs are soonest hatched which have been deposited in the shallowest water.

As the embryo is developed, the heart first appears, afterwards the spine, eyes, and tail. The organs of motion are evolved in the following order. The pectoral fins first make their appearance, and afterwards those of the tail; the dorsal fins follow, and then the ventral and anal fins.

Sexes distinct. Ovoviviparous.

2. *Ovoviviparous fishes, with the sexes distinct.* In this division are included the chondropterygii, and likewise a few osseous fishes. Sexual intercourse takes place, and the eggs are hatched in the uterus, and excluded along with the fry.

In the *males* of this division, at least in those of the chondropterygii, the testes are two in number, flat, of great extent, and situated between the spine and the stomach and intestines. Each is divided into two portions; the first resembles the soft milt of oviparous fishes, and the second consists of small spherical glandular bodies. From these an epididymis is produced, chiefly composed of convoluted tubes, which terminate in a vas deferens; the underpart of which is greatly dilated, and forms, as in birds, a considerable receptacle, or vesicula seminalis. Contiguous to the outer side of the dilated end of the vas deferens, there is a bag of considerable size, filled with a green liquor, which is discharged into the same funnel with the semen, and probably at the same time with it. By some, this is considered as a vesicula seminalis, while by others it is regarded as supplying the place of a prostate gland. The funnel through which the seminal fluid is poured, opens near the cloaca.

In the males of the chondropterygii, there are certain organs situated near the anus, consisting of bone, cartilage, and muscles. These were long regarded as the external organs of reproduction. But Rondeletius was of opinion that these were only accessory organs, and enabled the males to retain the females more closely during coition. The celebrated ichthyologist Bloch, from dissections, arrived at the same conclusion.

The late Mr Montagu has observed some peculiarities in the sexes of the skate, which deserve to be noticed. These are enumerated in the *Memoirs of the Wernerian Natural History Society*, vol. ii. p. 414. After speaking of the appendages at the base of the tail, he says, " Accompanying this truly masculine distinction, are series of large reclined hooked spines, never to be found on the other sex, and which begin to shew themselves early in all the species hitherto examined; these are placed in four distinct series, one on each shoulder or fore-part of the wing, or pectoral fin, and one on each angle of the wing. These spines are complete hooks resembling those used for fishing, and lie with their points reclined inwards in two or three, and sometimes four parallel lines, but the number of rows, and number in each row, depends on age; for in very young specimens, I have noticed only four or five spines in a single row. For what purpose this formidable armoury is given exclusively to the males, is not known, but as the hooks are extremely sharp, and lie partly concealed, with their points a trifle reflected, the fishermen's hands are frequently lacerated by incautiously handling the fish. These formidable spines, peculiar to the masculine gender, have occasionally been fixed on as a specific character; and as it does not appear to be generally known that it is only a sexual distinction, it has been thought proper to notice it for the advantage of others who may be pursuing the same track. There is another circumstance, which perhaps, in the discrimination of species, requires more attention than usual; that is, the teeth of both sexes of each species. The necessity of this is particularly evinced by the great difference observable in the teeth of the two sexes of the thornback, *Raia clavata*.

" In search of both sexes of this species, I was naturally led by the usually described essential character of the teeth being blunt, and I was not a little surprised when, amongst several hundreds examined, not one male could be found; but I noticed a ray, not unfrequently taken with the thornback, that was in every other respect similar, except that the wings were generally not so rough, and sometimes quite smooth about the middle. A variety also of this fish had an oblong dusky spot, surrounded with white, in the middle of each wing. The teeth of these fishes were not above half the size of those of the female thornback, and, except a few of the outer series on the lips, were sharp-pointed. For a long time I was puzzled to discover to what species of Raia these belonged, till, after an examination of a great number, I began to be as much surprised at not finding a female amongst such a quantity of these, as I was at not finding a male amongst those with blunt teeth. These circumstances naturally induced me to conclude, that the sexes of *clavata* had not been accurately defined, and that the leading character of blunt teeth might have been drawn from the female only. The fishermen had not noticed the distinction of the teeth in these fishes, and had considered all of them to be thornbacks. After much attention to the subject, and after having offered a premium for a male thornback with blunt teeth, an intelligent fisherman assured me, he had examined a vast number since I pointed out the distinction of the teeth, and that he could not find one instance of a male with blunt teeth, nor a female with sharp teeth. It may therefore be fairly inferred, that the sexes of the thornback actually differ in this particular, and that the male has probably been described as a different species, but under what title it is difficult to ascertain, unless it be Raja fullonica of some authors."

The male organs of the sharks and rays are such as we have now described; but few accurate observations have been made on the male organs of those ovoviviparous fishes, which belong to the branchiostegous and osseous tribes, such as the syngnathus, blennius, and muræna.

In the *females* of the sharks and rays, the ovaria, two in number, are situated at the sides of the spine, and contain ova of different sizes. From each of these proceeds an oviduct, the anterior extremities of which are united to the diaphragm and spine. Internally, these ducts are covered with glandular papillæ, and pass through a large glandular body. After passing this body, they dilate into a large sac, which is the uterus.

When the ova pass into the oviduct, they are carried to this glandular body, which is supposed to secrete the glaire or albuminous part, and afterwards conveyed to the uterus, where they receive the shell. At what period the egg becomes impregnated, or in what manner the operation is performed, are questions to which no satisfactory answers can be returned.

The eggs are of a quadrangular form, with processes at the four corners. By some they are called sea-mice, but by our fishermen they are known by the name of *skate* or *shark-purses*. The shell has a horny consistence, and may often be observed, at certain seasons, among the rejectamenta of the sea.

When the young fish have been perfected in the uterus, where they derive their nourishment exclusively from the egg, and not from the mother, they are ejected through the openings of each uterus, at the sides of the cloaca; and upon escaping from the shell, enjoy immediately an independent existence, and begin to search after new nourishment.

Hermaphrodites.

3. *Oviparous fishes which are hermaphrodite.* Instances of hermaphroditism among fishes, were for a long period considered rare, and always as accidental. Baster detected such an arrangement in the whiting, and Duhamel observed the same in the carp. But it was reserved for that able anatomist, Sir Everard Home, to point out a particular tribe of fishes in which the organs of both sexes are always present in the same individual.

Having been unsuccessful in obtaining any male lamprys, although he got what were considered as females in abundance, Sir Everard began to suspect that the individuals of the species were hermaphrodites, and his observation on these fish at different periods justified his conjectures.

“I found, (says he, *Phil. Trans.* A.D. 1815, Part II. p. 266), upon examination, that the two glandular bodies projecting into the belly, one on each side of the ovarium, which have always been supposed to be the kidneys, varied very much in size and appearance at the beginning and end of the season. When the ova are so small that the animal is reputed to be a male, these glandular bodies, and the black substance upon which they lie, appear to form one mass, and the duct upon the anterior part is thin and almost transparent, containing a fluid equally so; but in the end of May, when the ova increase in size, these glandular bodies become larger, more turgid, and have a distinct line of separation between them and the black substance behind; their structure is more developed, being evidently composed of tubuli running in a transverse direction, and the ducts leading from them are thicker in their coats, and larger in size.

“On the 5th of June, the ova were found to be of the full size; and a small transparent speck, not before to be observed, was seen in each; at this time the tubular structure had an increased breadth, and the duct going from it contained a ropy fluid, which, when examined in the field of the microscope, was found to be composed of small globules in a transparent fluid. On the 9th of June, neither the ova nor the tubular structure had undergone any change. On the 11th of June, the ova were of the same size, but the slightest force detached them from the ovarium; the tubular structure had increased still more in size, the fluid in the ducts was thicker, more ropy, and when water was added to it in the field of the microscope, it coagulated, and what was before made up of globules, had now the appearance of flakes. The ova do not pass out at an excretory duct as in fishes, but drop from the cells in the ovarium in which they were formed, into the cavity of the abdomen, and escape by two small apertures at the lower part of that cavity, into a tube common to them and to the semen in which they are impregnated.” In the lampern or pride, and in the gastrobranchus cœcus, a similar structure is observable.”

Although these observations leave little room to doubt that the animals in question are hermaphrodites, still it remains to be determined at what precise period, or in what position, the eggs are impregnated.

Castration.

Although the sexual organs of fishes had been long known, it was not until the middle of the 18th century that any experiments were performed to ascertain the effect of their abstraction. Tully appears to have been the first person who performed the operation, and an account of his experiments has been published in the *Gent. Mag.* vol. xxv. p. 416, and in *Phil. Trans.* vol. xlviii. When the abdomen of the fish is laid open, and the milt or roe carefully separated, and the wound sewed up again, the fish appears to experience but little pain, and the wound heals in a few weeks. These experiments have frequently been performed on the carp, and they are attended with little risk. The fish grows to a larger size, and its flesh is said to have a more delicate flavour. But castration has never come into general use among the proprietors of fish ponds, being seldom performed but from motives of curiosity or science.

Hybrid fishes.

We have already stated, that the impregnation of the egg takes place without the body of the female, and the experiments which have been conducted to establish this point, have likewise made us acquainted with the existence of *hybrid fishes*. Even in a common fish pond, where carp and trout are permitted to live in company, the carp sometimes impregnates the eggs of the trout, or the trout those of the carp. The limits, however, within which this irregularity is confined, have never been investigated with care.

Number of eggs.

Fishes exhibit very remarkable differences in regard to the *number of eggs* which they produce. The rays and sharks seem to prepare but a very limited number. Rondeletius states the number in the Squalus acanthias at six; other observers have found in other species 26 and even 30. But the number of eggs in other kinds of oviparous fish, exceeds almost our powers of reckoning. The following Table (*Phil. Trans.* 1767), may convey to the general reader some idea of their prolific powers.

Fish.	Weight.		Weight of spawn.	Number of eggs.	Season.
	Oz.	Dr.	Grains.		
Carp	25	5	2571	203109	April 4.
Cod-fish . . .	0	0	12540	3686760	Dec. 23.
Flounder . .	24	4	2200	1357400	March 14.
Herring . . .	5	10	480	36960	October 25.
Mackrel . . .	18	0	1223½	546681	June 18.
Perch	8	9	765½	28323	April 5.
Pike	56	4	5100½	49304	—— 25.
Roach	10	6½	361	81586	May 2.
Smelt	2	0	149½	38278	March 21.
Sole	14	8	542½	100362	June 13.
Tench	40	0	—	383252	May 28.

It appears evident, from this Table, that there is no regular proportion between the weight of the fish and the weight or number of eggs produced. Nor is there any estimated proportion between the number of eggs deposited, and the number of fish which arrive at maturity. The eggs are eagerly sought after by other fishes, by aquatic birds and reptiles. In the young state, they are pursued even by their own species, as well as by beings belonging to other classes. But for the numbers of eggs thus produced, the very race of fishes would soon be extinguished by enemies while young; and we may add, that the diminution of the number of eggs would cut off a large supply of food, and destroy that dependence which we observe in the polity of nature, of the different races of animals on one another.

The season in which fish deposit their eggs varies according to the species, and even the habit of the individual. It is well known that among salmon, even in the same river, a difference of some months is observable, and we believe that the same remark is applicable to all other kinds of fish. In general, before spawning, fish forsake the deep water, and approach the shore, that the roe being placed in shallow water, the influence of the solar rays may vivify it. At that season, some fish forsake the salt water, and ascend rivers, and after spawning, retreat again to the ocean.

The eggs of various species of fish belonging to the oviparous order, with distinct sexes, are used as articles of food. Where circumstances permit, they are consumed while in a recent state. In other situations they are salted, and form the well-known article of trade *caviar*.

The characters which the organs of reproduction furnish, in the discrimination of species, have been hitherto too much neglected. Connected as they are with the existence of the animal, and exercising a powerful controul over its habits, they ought to be examined with care, and their appearances recorded in detail.

SECT. XII. *Organs of Electricity.*

Organs of electricity.

FROM the remotest periods, the benumbing powers of the torpedo have been the subject of popular admiration. In the days of Aristotle and Pliny, some of its curious properties were ascertained; but it was not until the year 1772, that any accurate observations were made on the animal, conducted on scientific principles.

The resemblance between the sensation produced by the torpedo, and that occasioned by the discharge of a jar charged with electricity, was first pointed out by John Walsh, Esq. who determined, at the same time, many of the phenomena which accompany this action of the animal. Nearly about the same time, and in consequence of examples furnished by Walsh, Mr Hunter dissected this animal with care, observed the appearances of its electrical organs, and pointed out their relation to one another. Previous to these observations of Walsh and Hunter, Borrelli, Lorenzini, and Reaumur, had each of them examined the fish, and arrived at some accurate general conclusions. Since that time the subject has attracted the attention of other investigators, and may now be considered as having received more ample illustration than any other branch of the physiology of fishes.

The structure of the electrical organs of the torpedo and the other fishes which possess them, has been already fully explained under the article ELECTRICITY, to which we refer our readers. Since the publication of that article, Mr Tod (*Phil. Trans.* 1816, Part I. p. 120,) has investigated the influence of the nerves in the production of the electricity which these organs exhibit, and added some new facts to those which had been given to the public by preceding writers. He observes that the columns, when separate and uninfluenced by external pressure, appear to be of the form of cylinders, as is shown as nearly as possible by suspending them by one of their extremities. The different forms which they exhibit in a horizontal section of the whole organ, are produced by their unequal attachment to one another, by the intermediate reticulate substance. He adds, that the electrical organs are so placed within the curvature of the semilunar cartilages of the large lateral fins, as to be entirely under the influence of the muscles, which are inserted into these organs.

In order to ascertain the share which the nerves have in producing the phenomena, he made an incision on each side of the cranium and gills of a lively torpedo, and pushed aside the electrical organs so as to expose and divide their nerves. The animal was then placed in a bucket of sea water. On examining it in about two hours afterwards, he found it impossible to elicit shocks from it by any irritation; but it seemed to possess as much activity and liveliness as before, and lived as long as those animals from which shocks had not been received, and which had not undergone this change. Two of these animals being procured, the nerves of the electrical organs of one of them were divided after the manner above described. They were placed each in separate buckets of sea water, and allowed to remain undisturbed. This was performed in the morning, and when examined in the evening, it was impossible to distinguish between the liveliness or activity of either. Of other two of these animals, the nerves of the electrical organs of one of them were divided. Being placed each in separate buckets of sea water, they were both irritated as nearly alike as possible. From the perfect animal, shocks were received; after frequent repetition, it became weak and incapable of discharging the shock, and soon died. The last shocks were not perceptible above the second joint of the thumb, and so weak as to require much attention to observe them. From the other, no shocks could be received; it appeared as vivacious as before, and lived until the second day. This experiment was frequently repeated with nearly the same results. The nerves of one electric organ only being divided in a lively torpedo, from which shocks had been previously received, on irritating the animal, it was still found capable of communicating the shock. Whether there was any difference in the degree of intensity could not be distinctly observed. One electrical organ being altogether removed, the animal still continued capable of discharging the electric shock, and the same circumstance took place when only one of the nerves of each electrical organ was divided. When a wire was introduced through the cranium of a torpedo, which had been communicating shocks very freely, all motion immediately ceased, and no irritation could excite the electrical shock.

The shock is communicated through the same conductors as common electricity, and intercepted by the same non-conductors. The sensation may be communicated to several persons at the same instant; and it is of no consequence whether the animal be insulated or not. The shock, however, is much stronger in air than in water; in summer than in winter; when the animal is in vigour, than when in an exhausted state. The shocks generally follow simple contact or irritation; but, in some instances, when caught by the hand, no shock is discharged until muscular energy has been exerted in vain to extricate itself.

This electrical discharge is in general accompanied by an evident muscular action. There appears a swelling of the superior surface of the electrical organs, particularly towards the anterior part opposite to the cranium. The eyes also appear at the time somewhat retracted. If this action of the fish be too much excited, the animal becomes debilitated, and soon expires.

Spallanzani, while prosecuting his experiments on this subject, ascertained, that the young fish as well as the old possessed this power; and, what appears still more surprizing, even those still in the egg in the uterus were able to communicate a sensible shock.

Besides the torpedo, there are other fish which possess the same apparatus, and exhibit the same singular phenomena. One of these, the *gymnotus electricus*, has been carefully examined by Hunter; and the result of his observations, communicated in the 65th volume of the *Phil. Trans.* A third fish, the Silurus electricus, possesses the same property; and probably many more with which we are as yet unacquainted; although to this list there can only be added at present the *Trichiurus Indicus* and *Tetraodon electricus.*

The use of this singular faculty has often been pointed out both by ancient and modern naturalists. As an instrument of defence, the exercise of such a power will protect the fish from many of its foes; and when used in the offensive, it will be equally formidable. Such animals may be able to benumb their smaller and defenceless prey, and employ their electrical energies in procuring food.

The characters furnished by the organs of electricity were for a long time overlooked, and were not even permitted to constitute a generic distinction. The torpedo was long classed with the rays; and in many systems fishes with electrical organs, and such as are destitute of them, still belong to the same genus.

CHAP. III.

Condition of Fishes.

Condition of fishes.

The subjects which we propose to discuss in this Chapter are rather of a miscellaneous nature, and embrace a variety of circumstances connected with the natural and economical history of fishes. We shall divide the whole into eight sections, and in these treat of the distribution, migrations, education, naturalization, dietetical uses, and diseases of fish; and conclude with some observations on the geological data which they furnish, and the various methods which have been employed to preserve them in a museum.

Sect. I. *Distribution of Fishes.*

Distribution of fishes.

We have already stated, that fishes naturally reside in the water; but as this element is found to differ in its constitution and temperature according to its situation, we may expect to find the finny tribes that dwell in it influenced by these circumstances. At a very early period, the diversity in the distribution of fishes attracted the attention of observers. Rondeletius at last attempted a division of this class of animals, from the different situations in which they are found, into marine, fluviatile, lake, and pond fish. It will be more suitable to our present purpose, to consider them as inhabitants of the sea or of fresh water.

Salt water fishes.

The salt-water fishes are much more numerous than those which reside in fresh water. They cannot be distinguished from fresh water fishes by any peculiarity of structure, or external form. They are always found in the greatest numbers in tideways, and on those banks which are formed at the junction of opposite currents. They in general resort to a certain kind of bottom, in which we may suppose they find a plentiful supply of food. Some are always found near rocky shores, while others prefer the sandy bays. Some are found only in the open ocean, and are termed *pelagic*; others keep within a short distance of the coast, and are termed *littoral*. M. Risso, in the introduction to his *Ichthyologie de Nice*, (8vo. Paris 1810, p. xiv.) has the following interesting notices respecting the distribution of the fishes of the Mediterranean, which we shall give in his own words. "Ces grandes profondeurs sont hérissées de rochers et ne sont fréquentées que par les *Squales*, les *Balistes*, les *Chimères*, les *Ziphias*, les *Gades*, les *Caranx*, les *Centronotes*, les *Lepidolèptres*, les *Trigles*, les *Centropomes*, les *Holocentres*, les *Bodians*, les *Tetragonures*, les *Pomatomes*. A cent mètres des profondeur, en avançant vers la terre, les fond de la mer est recouvert de fange et de limon, séjour impur de *Raies*, des *Lophies*, des *Cepoles*, des *Zees*, des *Pleuronectes*, des *Oligopodes*, enfin de tous les poissons a chair molle et baveuse. En continuant de s'élever á cent cinquante mètres de profondeur, a peu pres, la végétation se manifeste: les algues, les caulinies, les ulves, les conferves, les varecs, et les zoophytes qui tapissent ce séjour, y appellent les *Ophidies*, les *Stromatées*, les *Murènes*, les *Uranoscopes*, les *Vives*, les *Scorpènès*, les *Peristedions*, les *Labres*, les *Spares*, les *Lutjans*, les *Esoces*, les *Murénophis*, &c. Viennent ensuite les rochers du rivage, ou les *Syngnathes*, les *Centresques*, les *Blennies*, les *Batrachoides*, les *Gobies*, les *Notoptères* font leur demure accoutomée. Enfin les belles plaines de galets et de sable ou se nourrissent les *Lépadogastères*, les *Ammodytes*, les *Callionymes*, les *Lepidopes*, les *Gymnètras*, les *Osmères*, les *Scombrésoces*, les *Argentines*, les *Atherines*, les *Stolephores*, les *Mugil*, les *Clupées*, et les *Serpes*."

These different depths at which fishes reside in the sea, may be regulated by the presence of suitable food in those places. When fishes live at a great depth, the air-bag secretes more oxygen than when residing near the surface; but this is a circumstance over which the fish perhaps can exercise controul; and although the pressure upon the body must increase with the depth in the water, we are ignorant of the effect produced on the sensations of the animal by the change. Even many pelagic fish become littoral during the breeding season, and the littoral fish retreat to the deep on the approach of a storm.

Fresh water fishes.

The fresh-water fishes are not so important, in an economical point of view, as those which inhabit the ocean. Some species frequent rivers, and seem to require, for the preservation of their health, a continued current of water. Others live in lakes, and seem contented to spend their days where the water is still. Like salt-water fishes, they appear to prefer particular altitudes; and in ascending mountains, we may observe that the fish in the lakes and rivers have their boundaries, as well as the vegetables which cover their surface. Thus Wahlenberg found, that the pike and perch disappeared from the rivers of the Lapland Alps along with the spruce fir, and when 3200 feet below the line of perpetual snow. Ascending 200 feet higher, the gwiniad and the grayling are no longer to be found in the lakes. Higher up still, or about 2000 feet below the line of perpetual snow, the char disappears; and beyond this boundary all fishing ceases.

When a salt water fish is put into fresh water, its motions speedily become irregular, its respiration appears to be affected, and unless released it soon dies. The same consequences follow when a fresh water fish is suddenly immersed in salt water. In what manner they are influenced by the change, has never been satisfactorily determined.

There are not a few fish which may be said to be *amphibious*, or capable of living either in fresh or salt water at pleasure. Such fish, in an economical point of view, are extremely valuable, as they furnish to the inhabitants of this and other countries an immense supply of food. The salmon may be given as an instance in this country, where, from one river, (Tay) 50,000 head of full sized fish have been obtained. To the Greenlanders, their Angmarsæt, or Salmo arcticus, is perhaps more valuable, as it is formed into bread, as well as consumed in a fresh or salted state.

All these fishes seem to reside chiefly in the sea. There they grow and fatten; but when the time of spawning approaches, they forsake the salt water, and return to rivers and lakes. But this desertion of the ocean is only temporary, and regulated by the circumstances connected with reproduction. The instant the spawning is finished, they repair with equal rapidity to the ocean, to repair their exhausted strength, and fit them for obeying again the laws of their existence. Some of these fishes appear to be capable of living exclusively in fresh water, when confined in a lake or river. We are informed in the statistical account of the parish of Lismore, when speaking of the fresh water lakes of that island, (*Stat. Acc.* vol. i. p. 485.) "That, about 50 or 60 years ago, there were some sea trouts carried to these lakes, the breed of which preserve their distinction perfectly clear to this day. They retain their shining silver scales, though they have no communication with the sea; their flesh is as red as any salmon, and their taste is totally different from that of the yellow trouts."

The circumstance of some fish being capable of living either in fresh or salt water, has suggested the idea of attempting to modify the constitution of salt water fishes, so as to enable them to subsist in fresh water. If the change is attempted to be produced in young fish by degrees, and with caution, the experiment may prove successful, especially with those fish that reside chiefly near the sea shore. But in the case of fishes which live in deep water, a change not only in the respiratory organs must be produced, but likewise in those of digestion, as they must subsist on a new kind of food. We regard such experiments as curious, but can scarcely bring ourselves to believe, that they will be productive of advantage to society. In attempting to improve our fisheries, we should prefer the prudent advice of Virgil to the dreams of the theorist—*et quid quæque ferat regio, et quid quæque recuset.*

We possess but few accurate observations on the distribution of fishes, with respect to *temperature*. Living in an element subject to little variation from the change of the seasons, fishes, like sea-weeds, have an extensive range of latitude as well as longitude through which they roam. But they appear to abound in the greatest variety of species in the equatorial regions, and to diminish in numbers with regard to species as we approach the poles. In this country we may observe a certain arrangement of some of the species with respect to latitude. Thus the fresh water fishes of England are much more numerous than those in Scotland. In the sea at the south of England, the pilchard is found in abundance, while it is rare in Scotland. In the seas in the north of Scotland, the tusk (*Gadus brosme*) abounds, in the south of Scotland it is very rare, and in England it is unknown.

While some fishes living in the northern seas, or in alpine lakes, seem to prefer cold water, there are fish which appear to dwell even in the waters of tepid springs. La Cepède informs us that Desfontaines found the *Sparus Desfontaines* in the warm waters of the two fountains which supply the town of Cassa in the kingdom of Tunis. The waters raised Reaumur's thermometer 30° above the freezing point, or about 100° of Fahrenheit. The waters contained no mineral impregnations, and when cooled, were used by the inhabitants.

Sect. II. *Migration of Fishes.*

Migration of fishes.

Those fishes which enter rivers for the purpose of spawning, perform their migrations annually, but do not appear at any very precise period. Their motions appear to be regulated by the condition of their generative organs, and these are in their turn controuled by the temperature of the water in which the fishes remain, or the supply of food. In rivers where salmon spawn, it is observed that these fish continue entering the river for the space of seven or eight months. Those marine fishes, such as the herring, pilchard, and many others which leave the deep water, and approach the shores for the purposes of spawning, are equally irregular with respect to their periods of appearing and disappearing.

Besides these movements, which depend on the generative impulse, many marine fishes appear to migrate from one shore to another, influenced by laws which have never been satisfactorily explained. Thus haddocks have been known to visit a coast for many years in succession, and then suddenly to disappear, and at the same time all those predaceous fish which fed upon them. Perhaps these movements may depend upon the supply of food, and be regulated by circumstances over which we can exercise no controul. Accurate observations, however, would probably ascertain the limits of these migrations, and enable us to derive advantage from motions which at present we regard as calamitous.

In the summer season, all the fresh water fish are active and lively; but during the winter, many species bury themselves in the mud, and, in a state of quiescence similar to natural sleep, outlive the vicissitudes of that variable season. While active they require a copious supply of food; but in this state of hybernation they continue fasting, and without inconvenience.

Sect. III. *Education of Fishes.*

Education of fishes.

The element in which fishes reside, removes them so far from our influence and observation, that it is difficult to estimate the amount, or the qualities of the immaterial principle which they possess. We witness them fly from danger, obey the impulse of appetite, and provide a suitable place for the eggs of their future offspring. These, however, are in general regarded as the lowest marks of mind, or as mere blind instinctive motions.

Fishes, we have seen, possess in a greater or less degree of perfection all those external senses, by means of which the other animals acquire a knowledge of external objects. Hence we find that they speedily become acquainted with the hand that feeds them, and know the face of a stranger. They may be taught to come to the edge of a pond when called by their usual name, or to assemble at the sound of a bell. Baster even informs us of a trout, which had been kept fourteen years and seven months, which would come and repose on the hand of its master while he removed the water of the vessel in which it was kept.

That they possess some powers of deliberation, appears evident from the artifices which they employ to escape from the nets in which they have been inclosed, or from the hook which they have incautiously swallowed. Salmon have been known to lie close on the ground in some hollow place, to permit the net to pass over them, or by a sudden spring to leap out of the net. The fishing frog, or angler, as it is also called, (*Lophius piscatorius*,) has two long tentacula on the head, resembling in appearance small worms. Having buried its body in the sand, leaving only these tentacula exposed, it moves them backwards and forwards, until the eye of some young fish is attracted by the deceitful appearance, and falls a prey to its lurking foe.

With regard to their social instincts, fishes present very remarkable differences. Some are gregarious at all seasons, while others are solitary unless during the breeding season. The sexual union is merely temporary, and no feelings of affection subsist between the parent and the offspring. Indeed the life of a fish is one continued scene of suspicion and fear, no leisure being left for the improvement of its faculties. Hence we are disposed to rank fish as the lowest link of the chain of vertebral animals,—to regard the powers of their immaterial principle, as controuled by the dangers to which they are exposed, and as almost exclusively occupied in supplying the wants which are connected with the first laws of existence.

Sect. IV. *Naturalization of Fishes.*

Naturalization of fishes.

In tracing the history of those attempts which have been made to subject this portion of the creation to our controul, we trace at the same time the progress of civilization and luxury. In Egypt, they had their sluices and their fish ponds in the days of Isaiah, (chap.xix. 10,) and from this early seat of the arts and sciences the Romans probably acquired the knowledge of rearing and feeding fish. During the more prosperous days of that refined people, almost every wealthy citizen had his fish ponds. In modern times, the Chinese bestow more attention on the cultivation of fish than perhaps any other nation. And in Europe, the importance of the subject has been duly appreciated by the Swedes, Prussians, and Germans. In the latter countries, a considerable part of the revenue from property is derived from the carp ponds.

Fresh water fish.

In general, the rearing of fresh water fish in artificial ponds has hitherto been chiefly attempted, few trials having been made to rear the salt water fish in confinement. In the construction of a pond for fresh water fish, care should be taken to have a regular supply of water free from mineral impregnations, to cover the deepest parts of the pond at least six feet. The more extensive the shallow ground at the sides is, especially if it be covered with marsh plants, so much more abundant is the supply of those minute animals, on which many fish chiefly subsist. Care should likewise be taken to introduce those small fish, which, by multiplying, may furnish a constant supply of food.

When fish ponds are formed, it is in general the wish of the proprietor to have a certain number of his stock in good condition, that he may have a regular supply for his table. For the accomplishment of this object, there is usually one pond set apart for the purpose, into which are introduced those full grown fish which he wishes to feed. During the winter season little food is required, but along with the heat of spring, fishes acquire a keen appetite, and at that period a constant supply of food should be given them. They should be fed morning and evening at a stated time, and always at the same place in the pond. The food should consist of any kind of corn, boiled or steeped in water for some time until it swells. Malt is esteemed a very fattening food, and the crumbs of bread steeped in ale; but peas are considered as little inferior to either. Pikes must have an abundant supply of eels, otherwise they require a long time to fatten. Some recommend the laying of dead carrion upon stakes in the middle of the water, that it may breed maggots, which falling into the water, furnish an abundant supply of very acceptable food.

In the construction and management of fish ponds, there are many circumstances of a local nature which it is impossible to specify. The methods employed to stock these ponds are at present more deserving of our attention. The first, and certainly the most obvious method, is to obtain living fish from similar situations. In catching these, the utmost care should be taken not to bruise them, or to rub off their scales, and to keep them as short a time out of the water as possible. The vessels in which they are to be carried should be full of water, as when the barrel is not entirely full, the fish are liable to be driven by the currents against the lid or sides. This transportation should take place only in cold weather, and in the winter season, (as fishes can bear cold better than heat,) and should be performed with as much expedition as circumstances will permit.

The second method of stocking fish ponds, is in some respects preferable to the preceding, especially when the waters are at a distance from which the supply is to be obtained. This consists in ascertaining those places in which the spawn of the wished for species is deposited, and conveying the impregnated eggs to a similar situation in the new ponds. In this manner a vast number of individuals may be obtained at once, and with great certainty of success, provided they are supplied during the journey with fresh water, and but little agitated. The impregnated eggs may be known by a small aperture, which may be detected on one side by means of a good microscope, and which is scarcely perceptible previous to impregnation. By means of this method, however, a much longer period must elapse ere fish are obtained for the table than by the former, although this objection is in a great measure obviated, by obtaining from the eggs a race of fish with constitutions accommodated to your waters.

The last method, which has been rather absurdly termed *artificial fecundation,* we owe to the ingenuity of M. Jacobi, (*Mem. de l'Acad. de Berlin.* 1764, *p.* 55.) It is founded on a knowledge of the mode of reproduction in oviparous fishes, and in its turn serves to illustrate the function of generation in fishes. In those places where the fish are easily procured, a female is obtained, whose roe is nearly ready for exclusion and having prepared a proper box with water, the fish is held by the head, with its tail downwards, and gently squeezed on the belly. The eggs which are perfect, readily run out into the vessel. A male fish is next obtained, and being held in a similar situation, the milt is poured upon the eggs. The eggs thus impregnated are conveyed to a proper situation as in the second method, and protected from those enemies which we have already enumerated.

The advantages which result from the translation and feeding of fishes have been felt and appreciated in other countries, but in our kingdom they have been in a great measure overlooked. In Scotland and Ireland, and we may likewise include England, there are multitudes of ponds and lakes, which are at present mere useless wastes, but which, if properly stocked with fish, would greatly contribute to the prosperity of the country, by furnishing an additional supply of food. To our forefathers we owe the introduction of two useful species of fish into the country, namely, the *carp,* which was translated (probably from France or Spain) into England about the year 1496, and the *pike,* which was naturalized about the beginning of the fifteenth century. The gold and silver fishes of China have likewise been naturalized in England, as objects of beauty. We wish this catalogue had been more extensive; we fondly hope that it will soon increase.

Salt water fish.

The formation of ponds for salt water fish, has often been the subject of speculation, but in few instances has it ever been reduced to practice. Indeed the motives for constructing such a pond must originate chiefly in curiosity, as those who are situated on a sea-coast, where such ponds can only be constructed, have access to that great storehouse of life, and may at all seasons derive from it an inexhaustible supply. Besides, there are few situations favourable for the construction of such a pond, and even where most favourable, an expensive barrier must be constructed to separate it from the sea. Some ponds of this kind have been constructed in Scotland. These are well described in the Scots Magazine for June 1816, p. 412.

" A good many years ago, a small fish pond, into which sea-water could be easily introduced, was constructed by an enterprising individual at Peterhead, in Aberdeenshire, (Mr Arbuthnot). A few sea fish were occasionally kept in it; but it soon fell into disuse, and it has of late been neglected. This however was, as far as we know, the first attempt of the kind in this country.

Since that time two sea-fish ponds, of greater dimensions, have been formed by private gentlemen in Scotland, for the conveniency of supplying their families. One of these is at Valleyfield, the seat of Sir Robert Preston, Bart. on the shore of the Frith of Forth; the other is situated in Wigton-shire, in an inlet called Portnessock, on the peninsular ridge of country called the Rins of Galloway, nine or ten miles south from Portpatrick, and is the property of Mr Macdowall of Logan.

At the spot where it is formed, there had originally been a small natural basin, communicating with the sea by means of a narrow sinuous fissure, or perhaps an empty vein in the rock. This basin has been enlarged and deepened, by working away the solid rock, which is grey wacke slate. At flood-tide, the water covers, to the depth of two or three feet, a ledge or walk which passes round an interior or deeper pond, and, at this time, allows tolerably ample space for the rapid motions of the fish.

The pond is replenished with fishes by the keeper, whose house is hard by. In easy weather, this man rows out in his fishing coble, to the mouth of Logan Bay, in which the inlet of Portnessock is situated. For catching the fish, he uses the common hand line, and the usual baits. He is provided with a wide tub, into which he puts a convenient quantity of sea water: to this tub he immediately commits such part of his capture as happen to be little hurt by the hook. He finds it necessary, during summer, to cover the tub with a cloth; and in sultry weather he experiences difficulty in keeping the fishes alive in the tub till he reach the shore. This, it seems evident, cannot be ascribed either to mere heat, or to the exhausting of the air contained in the water, by the respiration of the fishes. In all probability, it depends on the influence of the electric fluid of the atmosphere. De la Cepede, in his essay on the culture of fresh-water fishes, particularly mentions the powerful effect of this fluid on them, when confined in small portions of water, in the course of their transference from one place to another.

As might naturally be supposed, the fisherman prefers for the pond young fish, or at most those of middle size to those of large growth. In selecting cod-fish, for example, he rejects all that exceed 6lb. giving the preference to what he styles *lumps*, or young cod-fish, weighing 4lb. or 5lb. In the pond, the fish are not only preserved alive till wanted for use, but, being regularly fed, are found to be fattened. They are taken for use, however, merely by the line and hook; and it is probable, that the fish in best condition will not always be the first to catch at the bait.

The fishes we observed in the pond were the following:

1. Cod (*Gadus morhua*). They were lively, and caught greedily at shell-fish, which we threw into the pond. They kept chiefly, however, in the deep water, and, after approaching with a circular sweep, and making a snatch at the prey, descended out of sight to devour it. It has often been doubted, whether the red ware codling of Scotland was the young merely of the common cod, or a distinct species, *Gadus callarias*. Here one would think the question might easily be decided. Upon describing this red ware codling, we were assured that it occurs on the coast of Galloway, and that it had sometimes been caught and placed in the pond; but that, after a year, it became as large and as pale in colour as a common grey cod. This accords with our own observations, made in less favourable circumstances.

2. Hadock (*G. æglefinus*). These, contrary to expectations, we found to be the tamest fishes in the pond. At ebb tide, they come to the inner margin, and eat limpets from the hand of a little boy, the son of the keeper. They appeared white, and rather sickly. One was diseased about the eyes.

3. Coalfish (*G. carbonarius*). Some of these were of a large size, exceeding in dimensions the largest cod in the pond. No fish has received so many different names as the coalfish. When young, it is called at Edinburgh, podley; in the northern islands, sillock; in Galloway, blochan. When a year old, it is styled cooth, or piltock, in the north; and glasson in the south-west of Scotland. When full grown, it is named sethe in the north; and stenlock in the south-west. Accordingly we were now told, that " these stenlocks were mere blochans when they were put in." They were become of a fine dark purple colour. They were bold and familiar, floating about slowly and majestically, till some food was thrown to them: this they seized voraciously, whether it consisted of shell-fish, or ship biscuit. We were informed, that they too occasionally approach the margin, and take their food from the keeper's hand.

4. Whiting (*G. merlangus*). These were scarce in the pond, and very shy.

5. Pollack (*G. pollachius*). This was pretty common, and has been found to answer very well as a pond fish. It is generally called layde or lythe.

Besides these five species of gadus, we were told that the ling (*G. molva*) had occasionally been kept in the pond.

6. Salmon (*Salmo salar*). This was the wildest and the quickest in its motions of all the inhabitants. When a mussel or limpet, freed from the shell, was thrown on the surface of the water, the salmon very often darted forward and took the prey from all competitors, disappearing with a sudden jerk and turn of the body. I suspected this to be the salmon-trout (*S. trutta*); but was assured that it was the real salmon, which is occasionally taken in the bay.

7. Flat-fish, or flounders, of two sorts, were also in the pond; but they naturally kept at the bottom, and we did not see them. From the description given by the people, we concluded that they were dab and young plaise.

The food given to the fishes consists chiefly of sand-eels and of shell-fish, particularly limpets and mussels. In the herring-fishery season, they cut herrings in pieces for this purpose.

It is remarkable, that all the kinds of sea-fish above enumerated, seem to agree very well together. No fighting had ever been observed by the keeper, and seldom any chasing of one species by another.

None of the fish have ever bred: indeed, no opportunity of breeding is afforded to them. A warm and shallow retreat, laid with sand and gravel, would have to be prepared for some species; and large stones, with sea-weed growing on them, would have to be transferred to the pond, and placed so as to be constantly immersed in the water for the use of others. The dimensions of the present pond, however, are too circumscribed to admit of its being used as a breeding place. An addition for this purpose might, without much difficulty, be formed, and here some curious observations might be made. The spawn of various sea-fishes is frequently accidentally dredged up by fishermen, and could therefore no doubt be procured by using a dredge: its degree of transparency indicates whether it will prove prolific. This might be placed in a protected corner of the breeding pond, and its progress watched. On this branch of the natural history of sea fishes, little is known."

SECT. V. *Dietetical Uses.*

Dietetical uses.

FISH, considered as an article of food, is regarded as light, and easily digested, and therefore well suited for the young, the weak, and the sedentary. But for the same reason it is unsuitable food for those engaged in laborious occupations. Among the Romans, he who fed on fish was regarded as effeminate. It has often been considered, though perhaps without cause, as promoting the fertility of the human species; and the immense population of China has been ascribed to the abundant use of this kind of nourishment. Its tendency to encourage diseases of the skin appear to be universally acknowledged, and is indeed very evident in the remote islands of this country, of Faroe, of Iceland, and of Norway, where fish forms so great a proportion of the food of the inhabitants.

Previous to using fish as food, they have frequently to undergo some sort of preparation, varying according to the situation, the necessities, or the taste of the consumers. Where circumstances permit, they are in general used in a *fresh* state; and even in large cities, where the supply must be brought from a distance, various expedients are resorted to, to prevent the progress of putrefaction. By far the best contrivance for this purpose is the well-boat, in which fish may be brought to the place of sale even in a living state. Placing the fish in boxes, and packing them with ice, is another method, and has been extensively employed, particularly in the supply of the capital with salmon.

In many maritime districts, where fish can be got in abundance, a species of refinement in taste, at least a departure from the simplicity of nature, prevails, to gratify which, the fish are kept for some days, until they begin to putrefy. When used in this state, they are far from being disagreeable, unless to the organs of smell. Such fish are termed by the Zetlanders *blawn-fish.*

Where fish are to be found only at certain seasons of the year, various methods have been devised, in order to preserve them during the periods of scarcity. The simplest of these processes is to *dry* them in the sun. They are then used either raw or boiled, and not unfrequently in some of the poorer districts of the north of Europe, they are ground into powder, to be afterwards formed into bread.

But by far the most successful method of preserving fish, and the one in daily use, is by means of salt. For this purpose they are packed with salt in barrels, as soon after being taken as possible. When boiling them for the table, if the water be repeatedly changed, a great portion of the salt will be abstracted, and the fish rendered more palatable. In this manner are preserved herrings, pilchards, cod, salmon, and many other kinds of esculent fish.

In many instances, after the fish have been salted in vessels constructed for the purpose, they are exposed to the air on a gravelly beach, or in a house, and dried. Cod, ling, and tusk, so prepared, are termed in Scotland *salt-fish.* Salmon in this state is called *kipper,* and haddocks are called by the name of the place where they have been cured.

After being steeped in salt, herrings are in many places hung up in houses made for the purpose, and dried with the smoke of wood. In this state they are sent to market, under the name of *red-herrings.*

Although salt is in general employed in the preservation of fish, whether intended to be kept moist or to be dried, vinegar in certain cases is added. This is practised in this country, at least chiefly with the salmon sent from the remote districts to the London market. It can only be employed in the preservation of those fish, to which this acid is served as a sauce.

The flesh of fish is always in the highest perfection, or *in season* as it is called, during the period of the ripening of the milt and the roe. After the fish have deposited their spawn, the flesh becomes soft, and loses a great deal of its peculiar flavour. This is owing to the disappearance of the oil or fat from the flesh, it having been expended in the function of reproduction. When in season, the thick muscular part of the back, as it contains the smallest quantity of oil, is inferior in flavour, or richness, to the thinner parts about the belly, which are esteemed by epicures as the most savoury morsels.

There are some kinds of fishes, especially those which inhabit the shores of warmer countries, which are reputed *poisonous.* These are, the Tetraodon ocellatus, sceleratus, and lineatus, and the Sparus pagurus, and a few more. It is generally supposed, and with some probability, that the poisonous quality of these fish proceeds from the food on which they have subsisted. This conjecture is supported by the history of the mussel and the oyster, which owe their occasional noxious qualities to the zoophytes on which they feed. Perhaps the poisonous quality of these fishes might be considerably diminished, if not entirely removed, were the intestines carefully taken away, and the fish placed for a short time in salt brine.

SECT. VI. *Diseases of Fishes.*

Diseases of fish.

FISHES, in a domesticated state, are subject to various diseases, the cause and cure of which are not satisfactorily ascertained. Trouts, carps, and perches, are subject to various cutaneous diseases. During severe winters, when the surface of the ponds in which they are kept are frozen over, the various kind of fish seem to contract diseases, and, in such cases, great mortality often prevails. This seems to arise from want of air in the water, and can only be prevented by removing the fish to a deeper pond, through which there is a constant current. In some rigorous seasons, the extent of this mortality is most alarming, as, between 1788 and 1789, in some districts of France the inhabitants lost nearly all their stock of carp, pike, and tench. *Journal de Physique,* November 1789.

In the very same year, an epidemic distemper affect-

Condition of Fishes.

ed even those fish which live in the sea, as the following fact, communicated by the late Mr Creech of Edinburgh, in the Appendix to the sixth volume of the *Statistical Account of Scotland*, satisfactorily proves: "On Friday, 4th December 1789, the Ship Brothers, Captain Stewart, arrived at Leith from Archangel. The captain reported, that on the coast of Lapland and Norway he sailed many leagues through immense quantities of dead haddocks floating in the sea. He spoke several English ships, who reported the same fact."

Fishes are greatly tormented with intestinal worms. The common stickeback may be quoted as a remarkable instance. Its death is often occasioned by the increase of the *Tænia solida* of Gmelin; and it is even supposed, that the extinction of its existence by this parasite follows the function of reproduction with regularity. *Annals of Philosophy*, February 1816.

Fishes exhibit remarkable differences with respect to their *vivaciousness*. Thus some fishes expire almost the instant they are taken out of the water, as the herring, the smelt, &c. Others are capable of surviving hours and even days, when removed from their native element, as the eel, carp, and some others. It sometimes happens that vivacious fishes are conveyed to a distance by birds, and left, without being killed, on rocks or fields. This has given rise to many of the absurd stories which have been told of showers of fishes. Rondeletius observes with propriety, that those fishes whose gill openings are but imperfectly covered expire soonest when taken from the water; and those fish whose branchiæ are protected by a gill-lid which shuts close, or by a narrow opening, are most vivacious. The air soon dries the fine plumes of the branchiæ, and obstructs the process of respiration and of circulation.

Few accurate observations have been made to determine the *age* of fishes. The element in which they reside is supposed to preserve them from the pernicious influence of sudden changes of temperature; the slowness of the process of ossification; the coldness of their blood; and the tardiness of all their primary movements, are considered as indicating a lengthened existence. Accordingly we find, the age of the carp has been known to reach to 200 years, and the pike to 260.

The marks by which the age of fishes may be determined, have never been pointed out in a satisfactory manner. As the age of trees may be guessed at by the number of concentric circles in the wood, so it has been supposed that the age of fishes may be ascertained by the number of concentric circles in the scales or in the vertebræ. Such analogical reasonings are hurtful to science, as they occupy the place of observation. They have done so in this instance at least.

It is seldom that a fish is permitted to die a natural death, from old age. During every period of its existence it is surrounded by foes; and when no longer able to exercise its wonted watchfulness, or exert its powers of defence, it falls an easy prey to its more powerful adversaries. In a domesticated state, previous to death, the dorsal fins lose the power of maintaining the body in a vertical position, the levity of the belly, and the extraordinary distension of the air bag, reverse the natural position, so that the back becomes undermost, and the animal floats on the surface. Similar appearances present themselves, when the waters are contaminated by noxious mineral or vegetable impregnations.

SECT. VII. *Fossil Fish.*

Fossil fish.

The investigation of those changes which have taken place in the race of fishes since the formation of the globe, is attended with peculiar difficulty. The external form, on which in general the specific distinction is founded, is destroyed by pressure. All distinct traces of the softer parts have disappeared, and the geognost is left to draw his conclusions from the form of the teeth, or the outline and structure of the skeleton. Hence the conclusions which have been drawn respecting the particular species should be received with caution. In the newer rock formations, which have been termed *local*, such as the strata at Eningen, the remains of fishes have been observed, belonging to existing races, and still natives of the neighbouring lakes. But in the rocks of those formations which are called *universal*, the skeletons of fishes which have been found, in all probability belong to species now extinct. In examining the organic remains which we consider of this sort, it would appear that the teeth of unknown sharks are more numerous than those of any other description of fish. They are found in all the floetz limestones of this country, in company with the ancient camerated shells. Vertebræ of osseous fishes are chiefly found in the strata connected with the chalk formation, seldom in those of an older date.

Before concluding this chapter, it may not be unacceptable to the reader to be presented with a few observations on the *preservation of fishes for a museum*.

Method of preserving fishes for a museum.

The simplest method consists in dividing the fish vertically and longitudinally, taking care to preserve attached to one side the anal, dorsal, and caudal fins. From this side the flesh is then to be scraped off, the bones of the head reduced in size, the base of the fins made thinner, and the specimen then stretched out on pasteboard and dried. By this means a lateral view of the fish is preserved, and if the fins and gill-flap are cautiously spread out, the specimen will furnish sufficient marks for recognising the species. A collection of such fishes may be kept in a portfolio, similar to an herbarium.

Many species may be well preserved, by extracting the contents of the body at the mouth, or skinning the fish with the skin entire from the mouth towards the tail, in the same way as eels are prepared for cooking. Let it then be restored to its former position, fill the whole with fine sand, and having spread out the fins, let it be dried with care. Almost all wide-mouthed cylindrical or tapering fishes may be preserved in this manner. Some recommend filling the skin with plaster of Paris, while others employ cotton. Preserved fishes are usually covered with a coat of varnish, to restore in part the original lustre. But no means of this sort can retain many of the brilliant colours which the animals of this class possess; and even the form of some of the soft parts cannot be preserved. Hence fishes are in general preserved in bottles of spirits of wine. In this way, it is true, they take up much room, but they can be subjected to examination at pleasure, and all their characters satisfactorily exhibited.

CHAP. IV.

CLASSIFICATION OF FISHES.

Classification of fishes.

IN the last chapter, when treating of the structure and function of fishes, we endeavoured to point out the relative value of those characters which systematic ichthyologists have hitherto employed. We there gave it as our opinion, that the organs of respiration furnish characters which are obvious, permanent, and natural. By means of these characters, fishes may be divided into two great classes, viz. those with *fixed* and those with *free* gills; and the inferior divisions might depend on circumstances connected with the number, position, and structure of the accessory organs. But instead of attempting, in this place, to give a new system of ichthyology, we propose to lay before our readers a condensed view of the genera according to the system of La Cepede, the outlines of which have been already given in the historical part of this article. We propose to add occasional observations on the characters of these genera, and on the history of rare or useful species. In the account of species it is necessary to be concise, as an enumeration of all the known species of fishes, amounting to upwards of 1470, would swell the article to an inconvenient length.

SUB-CLASS I. CARTILAGINOUS FISHES.

Cartilaginous fishes.

In the fishes belonging to this sub-class, the skeleton never becomes so much indurated as to deserve the name of bone, but continues in the form of cartilage more or less compact. As this internal character cannot be discovered without the use of the dissecting knife, its employment in the formation of the primary divisions of a systematic arrangement has been justly condemned by many naturalists, and ought to be relinquished. The genera which are included under this division, exhibit great differences in the structure of their organs of respiration and reproduction.

DIVISION I.

The cartilaginous fishes of this division are destitute of a gill lid and gill flap. The gills are likewise fixed.

ORDER I. APODAL. *No ventral Fins.*

The structure of the animals of this very natural order has been ably investigated by Sir Everard Home, as we have already pointed out, while describing the organs of respiration and reproduction. They constitute the last link in the chain of fishes, and form the transition to the molluscous animals.

GENUS I. PETROMYZON. *Lamprey.*

Lamprey.

Seven gill-openings on each side of the neck, and an aperture on the top of the head.

The species of this genus possess an organ of adhesion on the lips, by which they attach themselves to stones; hence the name Petromyzon, from *πετρος*, *lapis*, and *μυζαω*, *sugo*. Lacepede enumerates nine species, three of which are British. They are distinguished by characters drawn from the form of the dorsal and caudal fins. All the species are vivacious, and may be kept in life for a considerable time when out of the water. The P. Planeri, found in the rivulets of Thuringia, when plunged into diluted alcohol, will survive upwards of a quarter of an hour; but it indicates, by its convulsive movements, the painful effects produced by the fluid on its organs of respiration. Some of the species are used as food, but principally for baits.

GENUS II. GASTROBRANCHUS. *Hag.*

Hag.

Gill-openings, two in number, situated under the belly.

This genus was formed by Bloch from the Myxine glutinosa of Linnæus. This last author placed it among his Vermes intestina; and the former, upon restoring it to its proper place among fishes, bestowed upon it a new name. Only two species are known.

ORDER IV. ABDOMINAL.

This is a very natural order. The species are ovoviviparous, and are distributed by Lacepede into three genera.

GENUS III. RAIA. *Ray.*

Ray.

Body depressed, five gill-openings on each side placed beneath, mouth under the snout.

This is a very extensive genus, including, according to La Cepede, thirty-six species. Some naturalists however, are disposed to regard a few of these as hybrid animals. Several new genera have been separated from it, particularly the genus CEPHALOPTERUS, which includes those species with a divided snout, and the torpedo, the characters of which we shall shortly notice. The species have been divided into several sections, from the form of the teeth, and the spines on the body; but the observations of Montagu appear to indicate these characters, as pointing out the differences of the sexes, not as sure marks by which the species may be distinguished. His remarks on this subject we have already stated under the head of *reproduction.* Many of the animals of this genus grow to a large size. They furnish a wholesome and palatable food, and are used either when fresh, salted, or dried. The spines of some are considered by the fishermen as venomous. One species, the R. Sephen of La Cepede furnishes, according to this author, the well known article of commerce termed shark's skin, or shagreen. This skin is covered with round hard tubercles, and, when dressed, is used to cover boxes or cases. The squalus canicula furnishes an inferior sort of skin, which is often used as a substitute, but the tubercles are smaller, and not so regular in shape.

GENUS IV. TORPEDO. *Cramp-Fish.*

Cramp-fish.

Body smooth, depressed, and obtuse before; five gill-openings on each side, placed beneath; electrical organs single on each side.

This genus, which has been lately revived, contains at present four species according to Risso; but the characters which separate them are far from being determinate. The best known species is the Raia torpedo of Linnæus, whose electrical organs have been already described under the article ELECTRICITY of this work.

GENUS V. SQUALUS. *Shark.*

Sharks.

Body round, tapering; gill openings from five to seven on each side of the neck.

This genus contains upwards of thirty species, whose characters and organs have not been described with sufficient attention. They exhibit very obvious differences in the structure of their organs of respiration, and on that account ought to be separated into several genera. The characters furnished by the organs of motion should be employed in forming the genera into sections.

The sharks are voracious and formidable; they possess great strength, and swim with considerable velocity. The smaller species are salted and dried, and used as food. The liver yields a considerable quantity of oil, and the skin of some species is used, on account of its roughness, to polish wood, brass, or ivory. It is likewise employed to make thongs and tackle for carriages. The teeth are employed by savages to point their arrows, and as a substitute instead of knives.

The species are all inhabitants of the sea, and are very widely distributed. Their teeth are found imbedded in limestone rocks of different ages, and seem to indicate that the sharks of the first ages were of a much larger size than those which now exist.

GENUS VI. PRISTES. *Saw-Fish.*

Saw-fish.

Snout produced, depressed, and furnished with a row of teeth on each side.

This genus, which Latham (*Lin. Trans.* ii. p. 273.) separated from Squalus, in imitation of the older naturalists, contains five species, distinguishable from one another by the appearances of the teeth in the snout. The most remarkable species is the Squalus pristes of Linnæus, now the P. antiquorum: the snout is frequent in collections. This animal grows to the length of fifteen feet. It is a native of the seas of both hemispheres. By means of its formidable snout, it attacks with success various kinds of whales, which it lacerates in a dreadful manner with its lateral teeth.

GENUS VII. SQUATINA. *Angel-Fish.*

Angel fish.

Body depressed, snout rounded, mouth terminal.

This genus was long recognised by naturalists. Linnæus united it to Squalus, and recently it has been revived. It contains only one species, the Squalus squatina of Linnæus. This is the *mermaid-fish* of Artedi, which, according to some naturalists, has given rise to those stories which we read and hear concerning mermaids. It is, however, more probable that there is a fish, not yet described by naturalists, of an amphibious nature, which has been occasionally seen on our coasts, and whose appearance, at a distance, bears some resemblance to the human form. For a description of one seen on the coast of Caithness, see the *Scots Magazine* for the year 1809, p. 734.

GENUS VIII. AODON.

Gill-openings, five on each side; mouth destitute of teeth.

La Cepede separated this genus from Squalus. It contains three species, whose characters have been but imperfectly described. Two of these were observed by Forskael in the Red Sea, and the third was observed by Brunich at Marseilles.

Sea snake.

At the conclusion of this account of the cartilaginous fishes with fixed branchiæ, we deem it expedient to direct the attention of the reader to the sea snake which was cast ashore on Stronsa, one of the islands of Orkney, in September 1808. The anatomical characters, furnished by the mutilated fragments which were sent to the Wernerian Society, seem to point out a connection with the genus Squalus. But the articulated fins on the sides, the form of the dorsal fin, and the lengthened neck, clearly prove the propriety of the new genus constituted for its reception, and termed HALSYDRUS, or sea snake. *Scots Mag.* 1809, p. 7.

The structure of the vertebræ of this animal has been explained with great precision by that celebrated anatomist Dr Barclay, and figures of some of the parts have been published from the accurate drawings of Mr Syme. These and the various descriptions of the animal sent from Orkney, have been given to the world in the first volume of the *Memoirs of the Wernerian Natural History Society of Edinburgh.*

DIVISION II.

Cartilaginous fishes, destitute of a gill-lid, but furnished with a gill-flap.

ORDER VI. JUGULAR.

GENUS IX. LOPHIUS. *Angler.*

Angler.

One gill opening on each side; mouth large and terminal.

This genus contains about eight species. Some naturalists appear disposed to leave in this genus those species in which the mouth is somewhat contracted, and to form another genus (Batrachus) of the wide-mouthed species. The L. histrio might in that case be considered as the type of the former, and the common fishing frog (L. piscatorius) as the representative of the latter. The flesh of the different species is soft, and seldom used as an article of food. Pliny remarks of the common angler, "that it puts forth the slender horns it has beneath its eyes, enticing by that means the little fish to play round, till they come within reach, when it springs on them." The skin of this animal, rendered transparent by oil, is sometimes used as a mask, with a candle burning in it, to represent the devil.

ORDER VII. THORACIC.

GENUS X. BALISTES. *File-Fish.*

File-fish.

Head and body compressed; about eight teeth in each jaw; gill-openings narrow.

In this genus La Cepede enumerates twenty-nine species. They chiefly inhabit the seas of warm countries. They are remarkable for the brilliancy of their colours, which are often gracefully disposed. The flesh is considered as poisonous.

ORDER VIII. ABDOMINAL.

GENUS XI. CHIMERA. *Sea-Monster.*

Sea-monster.

One gill-opening on each side of the neck; tail produced, and ending in a filament.

This genus consists of two species, a southern and a northern. The last of these has been repeatedly found in our seas.

DIVISION III.

Cartilaginous fishes, with a gill lid, but destitute of a gill flap.

ORDER XII. ABDOMINAL.

GENUS XII. POLYODON.

Teeth in the jaws and palate.

We owe this genus to La Cepede. It contains only one species, found preserved in spirits in the Parisian museum.

GENUS XIII. ACIPENSER. *Sturgeon.*

Sturgeon.

Mouth bearded before, without teeth, retractile, and placed under the head.

This genus contains only four species, but these are of considerable importance in an economical point of view; the sounds furnish isinglass and the roe caviar. They live in the sea, and at times ascend the rivers in troops. Their flesh is excellent and highly prized.

Classification of Fishes.

DIVISION IV.

Cartilaginous fishes, furnished with a gill-lid and gill-flap.

ORDER XIII. APODAL.

GENUS XIV. OSTRACION.

Body covered with an osseous coat of mail; cutting teeth in each jaw.

This genus contains fifteen species. They are easily recognised by the body being covered with an osseous plate, somewhat resembling a tortoise. They are all natives of the seas of warm countries. They feed upon the crustaceous animals, and some of the testaceous mollusca. The flesh is excellent, but small in quantity. La Cepede recommends the *O. triqueter* as a fish which he thinks might easily be naturalized in our seas. The *O cubicus,* a native of the Indian seas and the Isle of France, is often kept in pools, where it soon becomes so familiar as to come to the surface and eat from the hand. Its flesh is esteemed a great delicacy.

GENUS XV. TETRODON. *Sun-Fish.*

Sun-fish.

Jaws bony, extending, divided at the tip into two teeth; gill-opening linear; body round.

The fishes of this genus, have obtained their present name from the double teeth with which their jaws are furnished. La Cepede describes nineteen species, some of which are natives with us. They have the singular power of inflating their abdominal cavity at pleasure. The inflation is produced by air sent from the gills, into a sac formed of a duplicature of the peritoneum, and from thence into the abdomen. The inflation aids the animal in rising in the water, and as the abdomen is in some species covered with spines, it brings these organs of defence into a more favourable position for resistance.

GENUS XVI. OVOIDES.

Jaws bony, extended, divided at the tip into two teeth, destitute of dorsal, anal or caudal fins.

The single species, for the reception of which Lacepede formed this genus, was found described among the manuscripts of Commerson. It is an inhabitant of the Indian seas.

GENUS XVII. DIODON. *Globe-Fish.*

Globe-fish.

Jaws bony, extended, undivided.

The globe fish are but few in number, La Cepede having described only six species. They are natives of warmer seas. They are covered with long and formidable spines, like a hedgehog, and often exhibit a rich variety of colours. The *D. atinga,* a native of the tropical seas, is one of those fish considered by navigators as noxious. According to Pison, the gall is so virulent as to produce nearly instantaneous death in those that eat the parts of the fish where any of it has been spilt. The sound of the same fish, however, produces an isinglass, equal in quality to that which is obtained from the Acipenser huso.

GENUS XVIII. SPHEROIDES.

Body globular, four teeth or more in the upper jaw, no dorsal, anal or caudal fins.

La Cepede formed this genus for the reception of a species drawn by Plumier, and supposed to live in the sea on the east coast of America.

Classification of Fishes.

GENUS XIX. SYNGNATHUS. *Pipe-Fish.*

Pipe-fish.

Head produced, mouth small and terminal, furnished with a lid, no teeth; gill-openings on the neck.

The species of this genus have never been determined in a satisfactory manner. Even the British species are in confusion. There are eight species described, and some varieties; but it is probable that the characters of the sexes have been hastily considered as marks of distinct species.

It appears from the observations of naturalists, that the species of this genus belong to the ovoviviparous division of fishes, or those which hatch their eggs internally. Their bodies are covered with osseous plates like a coat of mail.

ORDER XV. THORACIC.

GENUS XX. CYCLOPTERUS. *Sucker.*

Sucker.

Mouth furnished with sharp teeth; ventral fins united; between these there is an organ of adhesion.

There are upwards of twelve species of this genus known. They may be distributed into sections from the union or separation of the caudal, dorsal and anal fins. They inhabit the sea, but are occasionally found in the mouths of large rivers. Their flesh is soft and oily, and eagerly sought after by seals. Some of the species, in a few hours after death, dissolve into a homogeneous gelatinous mass.

GENUS XXI. LEPADOGASTER.

Tentacula four before the eyes; organs of adhesion double.

We are indebted to Gouan for a knowledge of the only species of the genus, which he found in the Mediterranean. It has since been observed, in other seas, by many naturalists.

ORDER XVI. ABDOMINAL.

GENUS XXII. MACRORINCHUS.

Snout produced; jaws furnished with teeth; scales on the body small.

This genus was formed by La Cepede, and contains one species discovered by Osbeck in his voyage to China, and described by him.

GENUS XXIII. PEGASUS.

Snout produced; jaws furnished with teeth; body covered with large osseous plates.

The first notice of this genus was given by Ruyschius. It now contains three species. These have the pectoral fins uncommonly large, and are capable of supporting themselves for some time in the atmosphere. They are all of a diminutive size, and live in the seas of warm climates.

GENUS XXIV. CENTRISCUS. *Trumpet-Fish.*

Trumpet-fish.

Jaws without teeth, snout produced; body compressed; ventral fins united.

La Cepede describes three species belonging to this genus, viz. C. scutatus, velitaris, and scolopax.

SUB-CLASS II. OSSEOUS FISHES.

Osseous fishes.

All the osseous fishes have free branchiæ. With a few exceptions, they are oviparous. They appear to

Classification of Fishes.

be the most numerous as well as the most perfect of those animals which breathe by means of gills.

Division V.

Osseous fishes furnished with a gill-lid and a gill-flap.

Order XVII. APODAL.

Genus XXV. Cæcilia.

No fins; opening of the gills under the neck.

This genus was instituted by La Cepede, for the reception of the Muræna cæca of Gmelin. It is destitute of eyes on the exterior, and its true place in the system has not been satisfactorily determined. It is probable that it has fixed branchiæ, and is nearly related to the Gastrobranchus.

Genus XXVI. Monopterus.

A caudal fin, but destitute of all others; gill openings situated between the eyes.

The only species of this genus, is described by La Cepede from the manuscripts of Commerson. It is a native of the Indian seas.

Genus XXVII. Leptocephalus.

Anal and dorsal fins, but no pectoral or caudal ones; head small, body greatly compressed.

This genus was instituted by Gronovius, from an example sent to him by Pennant. This last author obtained it from Holyhead, through the kindness of Mr Morris. Donovan seems disposed to consider this as a spurious genus, and to conclude that the Leptocephalus morrisii is nothing more than a young and mutilated example of the Blennius gunnellus. But the late additions which have been made to the history of the L. morrisii in the new edition of the British Zoology, and by Montagu in the Memoirs of the Wernerian Society, vol. ii. p. 437, have removed all doubts on the subject. M. Risso is inclined to add another species to this genus, termed L. Spallanzani; but the shape of the body is so dissimilar, being cylindrical, that we fear it does not belong to this genus.

Genus XXVIII. Gymnotus.

Destitute of dorsal and caudal fins, but furnished with pectoral and anal fins.

This genus includes six species, the most remarkable of which is the G. electricus, which possesses the same benumbing power as the torpedo, and whose history has been given in detail under the article Electricity, vol. viii. p. 472.

Genus XXIX. Trichiurus. *Blade-Fish.*

Blade-fish.

No caudal fin; body compressed; gill lids placed near the eyes.

This genus contains two species. The first, T. electricus, is distinguished by its electrical properties. It is a native of the Indian seas, and was first described by Willoughby under the title Anguilla Indica. The second species, T. lepturus, inhabits the fresh waters, and probably ought to be separated from the former, as it is destitute of electrical organs.

Genus XXX. Notopterus.

Pectoral, anal, and dorsal fins present, no caudal fin; body very short.

The two known species which constitute this genus, were formerly included among the Gymnoti; but the presence of pectoral fins is a sufficiently obvious line of distinction. The first species, N. kapirat, of La Cepede, is a native of the seas at Amboyna. It is there named Pengay, or Kapirat. This last has been employed as the trivial name in the system, in defiance of the established maxims of the science. The second species is the N. squamosus, a native likewise of the Indian seas.

Genus XXXI. Ophisurus.

No caudal fin; body and tail cylindrical, and long in proportion to the thickness; head small; nostrils tubular.

The three species of this genus have been called by fishermen sea serpents, from their form and motions. They twist themselves in various directions with astonishing facility, and, when swimming, perform all their evolutions like the serpents. The O. ophis is a native of the European seas. The second, O. serpens, is found in greatest abundance in the Mediterranean.

Genus XXXII. Triurus.

Snout extended like a tube; one tooth in each jaw; caudal fin very short.

The only known species of this genus was found by Commerson in the south seas, and termed by La Cepede, T. Bougainvillianus. In its general aspect and size it bears a considerable resemblance to the common herring. He first observed them in the stomach of other fishes of the genus Scomber, which he had opened immediately upon being caught. We mention this fact, for the purpose of informing the inexperienced ichthyologist, that in such situations he may often meet with some of the rarest objects of his pursuit, and in a condition still fit for a minute examination.

Genus XXXIII. Apteronotus.

Jaws fixed; no dorsal fin; possessing a caudal fin.

La Cepede formed this genus for the reception of the Gymnotus albefrons of Gmelin, whose trivial name he has changed for that of Passan, by which it was designated by Daubenton. It presents some peculiarities of structure, which merit an attentive examination. From the upper part of the body, between the dorsal fin and the head, there issues a fleshy filament, which, after diminishing somewhat in size, and describing an arch, becomes again united with the body near the organ of the caudal fin. The filament is convex above and concave below, and is connected throughout its whole length by twelve short oblique filaments to the subjacent furrow into which it is received.

This curious species was first described by the celebrated Pallas, from a specimen in the collection of the Petersburgh Academy. Afterwards La Cepede added to its history, having had an opportunity of examining a more perfect specimen in the museum at Paris.

Genus XXXIV. Regalecus.

With pectoral, dorsal, and caudal fins; no anal fin, nor spines in place of it; body and tail lengthened.

There are two species belonging to this genus. The one inhabits the northern seas, and in Norway is called King of Herrings. It was first particularly described by Ascanius. It is very nearly related to the genera Ophisurus and Trichiurus. The other species, R. lanceolatus, has been described from a Chinese drawing of a fish in the Dutch collection.

GENUS XXXV. ODONTAGNATHUS.

On each side of the upper jaw a long curved jagged plate. This genus contains only one species, the O. mucronatus. It was obtained from Cayenne, where it is known under the name of Sardine. It lives in salt water, and is considered as good food.

GENUS XXXVI. MURÆNA. *Eel.*

Eel.

Body furnished with pectoral, dorsal, caudal, and anal fins; nostrils tubular; eyes covered with the common integuments; body serpentine and viscous.

It is a matter of regret, that the history of the species of this genus should still be involved in obscurity. The common eel is considered by some as oviparous, by others as ovoviviparous, and the opinion of ichthyologists is equally divided with regard to the reproductive organs of the conger. The species are very extensively distributed, being found in various parts of the new and old world. Their flesh is used as food, but is considered as difficult to digest. The skins are employed in place of ropes.

GENUS XXXVII. AMMODYTES. *Launce.*

Launce.

Head slender; caudal fin distinct from the dorsal and anal ones; upper lip doubled in.

This genus contains only one species, which is a native of the European seas. Its trivial name tobianus has been changed by La Cepede into *alliciens,* from its being a tempting bait, we presume, to other fishes. We cannot censure too severely such unnecessary innovations, as they perplex the student, and encumber the science with a load of useless synonymes.

GENUS XXXVIII. OPHIDIUM.

Head covered with large scales; body and tail compressed and covered with small scales; gill-flap very large; dorsal, anal, and caudal fins united.

According to La Cepede, there are three species belonging to this genus, two of which are natives, and the third was found by Fabricius in Greenland. He distributes them into two sections. In the first is placed the *O. barbatum,* having a beard; and, in the second, the *O. imberbe* and *unernak,* which are destitute of a beard. Risso, in his *Ichthyologie de Nice,* has described a fourth species which belongs to the first section, which he terms O. vassali. It differs from the O. barbatum in the four filaments of the beard being equal.

GENUS XXXIX. MACROGNATHUS.

Upper jaw produced; body and tail compressed; caudal fin distinct from the dorsal and anal fins.

La Cepede instituted this genus for the reception of the Pentophthalmus of Ray, and another fish which was found in the Dutch collection. The name of Ray ought to have been employed from its claims to priority. The M. aculeatus is found in the Indian seas, and its flesh is considered good.

GENUS XL. ZIPHIAS. *Sword-Fish.*

Sword-fish.

Upper jaw produced; blade-shaped; equal at least to one-third of the length of the body.

There are two species described by La Cepede as belonging to this genus, viz. *Z. gladius* and *ensis.* Some circumstances appear to favour the supposition that a third species exists, which has been confounded with the gladius. After having, however, examined the figures and descriptions of several authors, in connection with this subject, we feel ourselves at a loss to offer a decided opinion. The reader will find some judicious remarks on the subject in the *Scots Magazine for July* 1811, and in the *Memoirs of the Wernerian Society,* vol. ii. p. 58. In the last work, there is a figure of what is considered as the new species, which will, we hope, create the curiosity of naturalists to examine the subject.

GENUS XLI. MAKAIRA.

Snout produced; two osseous lanceolate shields on each side of the extremity of the tail.

La Cepede formed this genus for the reception of a fish thrown ashore at Rochelle. The fishermen called it Makaira.

GENUS XLII. ANARCHICAS. *Wolf-Fish.*

Wolf-fish.

Head rounded; upwards of five conic fore-teeth in each jaw; grinders flat and round; one long dorsal fin.

Three species of this genus are known to naturalists. They inhabit chiefly the boreal regions, and furnish a palatable food to the inhabitants.

GENUS XLIII. COMEPHORUS.

Body long and compressed; head and mouth large; rays of the second dorsal fin furnished with long filaments.

The only known species of this genus was found by the celebrated Pallas in the Lake Baikal.

GENUS XLIV. STROMATEUS.

Body greatly compressed and oval.

This genus contains five species, some of which are found in the Mediterranean, and others in the equatorial seas. The S. fiatola is the one which has been longest known, and is remarkable for the agreeable brilliancy of its colours. It inhabits the Mediterranean and Red Seas. The *S. paru,* which is frequent on the coast of Tranquebar, is esteemed delicate food, its flesh being white and tender.

GENUS XLV. RHOMBUS.

Body compressed and short; each side of the animal appears like a rhomboid; rays of the dorsal and anal fins not articulated.

The only known species of this genus was brought to Linnæus from Carolina by Dr Garden, and by him inserted in the genus chætodon. The skin appears to the naked eye to be entirely destitute of scales.

ORDER XVIII. JUGULAR.

GENUS XLVI. MURÆNOIDES.

Ventral fins consisting of one ray; gill-flap of three rays; body lengthened and compressed.

This genus was formed by La Cepede for the reception of the Blennius murænoides of Gmelin. It forms a sort of connecting link between the apodal and the jugular fishes of this division.

GENUS XLVII. CALLIONYMUS. *Dragonet.*

Dragonet.

Head larger than the body; eyes near each other; gill openings on the neck; ventral fins distant; scales minute.

There are five species of dragonets described by naturalists; but it is probable that this number will be reduced when the sexual differences are better known. Mr Neill, to whose ichthyological labours we have already alluded, has ascertained that the Linnæan Cal. Dracunculus is merely the female of the Cal. Lyra. "In the course," says he, "of dissecting and preserving some of each, (viz. the sordid and gemmeous dragonet), it struck me, as remarkable, that the gemmeous dragonets were all males, and the sordid dragonets all females. I now considered it as a fortunate circumstance that numbers were brought to me, presuming that if I should find the gemmeous dragonets to be uniformly *milters*, and the sordid dragonets to be uniformly *spawners*, I might be permitted to conclude that they are only male and female of one and the same species. I accordingly opened every specimen which I received to the amount of some dozens, and the result entirely supported that opinion. Both sorts were brought to me nearly in equal numbers; and from the fishermen I learned that they were taken promiscuously on the same lines." *Memoirs of the Wernerian Natural History Society*, vol. i. p. 530.

GENUS XLVIII. CALLIOMORUS.

Gill-openings on the sides; head larger than the body; ventral fins distant; scales minute.

The Callionymus Indicus of Gmelin is the only known species of the genus. It is a native of Asia.

GENUS XLIX. URANOSCOPUS. *Star-Gazer.*

Star-gazer. Head depressed; eyes on the head contiguous; edges of the gill-lid ciliated.

The position of the eyes in the fishes of this genus is very remarkable, and has procured for them the generic names which are prefixed. There are two species. The first species, *U. mus* of La Cepede, the *U. scaber* of Gmelin, is an inhabitant of the Mediterranean. It lives near the shore, and, concealing itself in the mud, moves the filaments of the beard, so as to imitate the motions of a worm, and in this manner entices the small fish to their destruction. Its flesh is white, but dry and disagreeable. Its bile was considered by the ancients as useful to heal wounds. The U. Japonicus, first described by Houttuyn, is found in the seas near Japan.

GENUS L. TRACHINUS. *Weever.*

Weever. Head compressed and spinous; gill covers spinous; anus near the breast.

This genus contains three species, two of which are found in the British seas. The spines of the dorsal fin of the common weever are supposed by our fishermen to contain a venemous fluid, as the wounds occasioned by them are exceedingly painful, and attended with a considerable degree of inflammation.

GENUS LI. GADUS. *Cod.*

Cod. Head smooth, compressed; gill lid, of many pieces, margined with a smooth border; ventral fins slender, and ending in a point.

This is the most important genus, in an economical point of view, in the whole system. All the species are esculent and palatable, and furnish to the human race a valuable supply of nourishment. Besides the flesh, the liver is used to extract the oil which it contains; the roes are salted as a kind of caviar; and the air-bladder yields isinglass. They are gregarious, and are chiefly to be met with in the temperate and cold climates. The species exceed twenty in number, and exhibit such remarkable differences in the number and form of their organs of motion, that we are surprised at still finding them included in the same category.

GENUS LII. BATRACHOIDES.

Head depressed and large; opening of the mouth wide; around and below the under jaw, a beard.

This genus was formed by Lacepede, for the reception of two species from the genera Gadus and Blennius. The first is the Gadus tau of Gmelin. It is found in the Atlantic ocean, and was first accurately described by Bloch. The second is the Blennius raninus of Gmelin, the Gadus raninus of Muller.

GENUS LIII. BLENNIUS. *Blenny.*

Body and tail lengthened and compressed; head blunt and steep: ventral fins consisting of from two to four united rays. Blenny.

This genus contains, according to La Cepede, twenty-three species. Some of the species at least are ovoviviparous, or hatch the eggs internally, and exclude them along with the young fish, while others appear to be simply oviparous. The genus formed by Artedi was named from Βλεννα, mucus, to indicate the slimy nature of their skin. La Cepede distributes them into sections, according to the number of the dorsal fins and the condition of the head. Into his last section, or those with one dorsal fin and no tentacula, he has inserted the Gadus brorme under the title Blennius Torsk, although he had previously given the species under the cod genus.

GENUS LIV. OLIGOPODUS. *Spotted Blenny.*

One dorsal fin extending from the head to the tail; one ray in each ventral fin. Spotted Blenny.

This genus contains the *Coryphæna velifera* of Gmelin, a fish first described by Pallas. It is a native of the Indian seas.

GENUS LV. KURTUS.

Body greatly compressed, and carinated above and below; back arched.

We are indebted to Bloch for the formation of this genus, which contains only one species, termed by him *K. indicus.* La Cepede has changed the trivial name into *Blochianus.* It is a native of the Indian seas, and feeds on crustaceous and testaceous animals.

GENUS LVI. CHRYSOSTROMUS.

Body and tail arched; compressed; one dorsal fin.

Rondeletius described the only species of this genus known to naturalists, under the name Fiatola.

ORDER XIX. THORACIC.

GENUS LVII. LEPIDOPUS.

Body lengthened, blade-shaped; ventral and anal fins consisting of one ray.

Gouan of Montpellier, formed this genus, and described for the first time the only known species.—L. argenteus. Shaw in his General Zoology, without being aware of the previous labours of Gouan, formed his genus *Vandellius* for the reception of a species differing in some respects from the fish of Gouan, but of the same genus. Montagu, inattentive equally to the labours of Gouan and Shaw, formed his genus *Ziphotheca* for the reception of a species of Lepedopus, similar to the one which Shaw describes. He had considered his fish as belonging to the apodal order, not supposing that the pair of ventral scales, though destitute of motion, were regarded as the rudiments of ventral fins. We are disposed to consider this genus as consisting, at present, of four species. The L. argenteus of Gouan, termed Gouanianus by La Cepede—L. tetradens, the Ziphotheca tetradens of Montagu, and the Vandellius argenteus, caudafurcata of Shaw.—L. Peronii and L. pellucidus of Risso.

GENUS LVIII. HIATULA.

No anal fin.

The H. Gardeniana of La Cepede, and the only known species, is the Labrus hiatula of Linnæus. It was observed by Dr Garden in South Carolina.

GENUS LIX. CEPOLA. *Band-Fish.*

Band-fish.

An anal fin; more than one ray in each ventral fin; body long and blade-shaped; belly scarcely the length of the head.

This genus was first characterised by Bloch. It contains three species, whose specific differences are far from being distinctly marked. The C. tenea and rubescens (whose trivial name La Cepede, with his usual fondness for innovation, has changed into serpentenformis,) are found in the Mediterranean, while the third species, *trachyptera*, has been hitherto observed only in the Adriatic gulf.

GENUS LX. TÆNIOIDES.

An anal fin; pectoral fins disc-shaped; body long, blade-shaped; belly scarcely the length of the head: eyes indistinct; no caudal fin.

The genus contains one species, the T. Hermannii, of whose habits or station nothing is at present known. The trivial name which La Cepede has bestowed upon it, is in honour of Professor Hermann of Strasburgh. The eyes are so very small that they can scarcely be distinguished. They appear like black points.

GENUS LXI. GOBIUS. *Goby.*

Goby.

Ventral fins united; two dorsal fins.

La Cepede distributes the twenty-two species of which the genus consists into two sections, from circumstances connected with the attachment of the pectoral fins. All the species are diminutive in point of size, and have failed to attract the notice of the epicure. A few species, however, are used as food. The G. *lanceolatus* is said to have a very pleasant taste. It lives in the rivers and streams in Martinique.

GENUS LXII. GOBIOIDES.

Ventral fins united; one dorsal fin; head small; the gill-lid attached nearly throughout its margin.

La Cepede has constructed this genus from species which formerly belonged to the genus gobius. The first species which he describes is the gobius anguillaris of Gmelin, a native of the Equatorial seas.

GENUS LXIII. GOBIOMORUS.

Ventral fins distinct; two dorsal fins; head small, eyes approaching; gill-lid attached nearly throughout its margin.

The genus contains four species. The first has been long known to naturalists, and is the Gobius gronovii of Gmelin.

GENUS LXIV. GOBIOMOROIDES.

Ventral fins distinct; one dorsal fin; head small; the gill-lid attached nearly throughout its margin.

The Gobius Pisonis of Gmelin is the only known species of the genus. It was first described by Piso in his Natural History of Brasil.

GENUS LXV. GOBIESOX.

Ventral fins distinct; one dorsal fin, short, and placed on the tail near the caudal fin; head larger than the body.

The G. cephalus, of which the genus consists, is a native of the American rivers, and was first described by Plumier.

GENUS LXVI. SCOMBER. *Mackrel.*

Mackrel.

Two dorsal fins; spurious fins in front of the tail above and below; sides of the tail carinated on the ends of the lateral line.

This important genus contains fourteen species, two of which are natives of our seas. Many of the species exhibit the greatest variety and beauty of colour, and almost all furnish wholesome food. The flesh of the common mackrel is somewhat greasy; and from it the Romans expressed a *garum* or pickle, which was esteemed not only as an agreeable seasoning, but as a valuable medicine.

The Scomber germo of La Cepede, which is found in great abundance in the Pacific ocean, proves extremely palatable and wholesome to sailors. Commerson observed that the shoals of this species did not approach indiscriminately all the vessels of the fleet, but chiefly those which had been long at sea, and whose bottoms were foul. The same observer supposes that fishes often approach ships in the equatorial seas, enticed by their shadow in the water, which screens them from the direct influence of the sun beams.

GENUS LXVII. SCOMBEROIDES.

One dorsal fin, with spines in front; spurious fins above and below in front of the caudal fin.

La Cepede, who formed this genus, has described three species. The *S. Noelii* has ten spurious fins above, and fourteen beneath. The *S. Commersonianus* has twelve spurious fins above and beneath, while the S. saltator has only seven above and eight beneath. The second species is from the shores of Madagascar; but the habitation of the others is unknown.

GENUS LXVIII. CARANX. *Scad.*

Scad.

Two dorsal fins; no spurious fins; sides of the tail carinated.

This was instituted by Commerson, and so named from *καρα*, *caput*, in reference to the size, the power, and the lustre of that part of the body, and the dominion exercised by the species of this genus over their weaker neighbours. The genus contains twenty species, which La Cepede has distributed into two sections. In the first are placed those which have no spines between the dorsal fins; and in the second, such as are furnished with spines in that place. Many of the species are from the Red sea, and present few particulars worthy of being mentioned.

GENUS LXIX. TRACHINOTUS.

Two dorsal fins, with spines concealed in the front of these under the skin.

This genus was formed by La Cepede from *τραχινος*, *asper*, in reference to its dorsal spines. It contains only one species, the T. falcatus, first described by Forskael in his Fauna Arabica. Commerson likewise observed it on the shores of Madagascar.

GENUS LXX. CARANXOMORUS.

One dorsal fin; no spurious fins; upper lip fixed.

This genus is nearly allied to the preceding, and contains 4 species, formerly included in the genus Scomber.

GENUS LXXI. CÆSIO.

One dorsal fin; upper lip extensile.

The species contained in this genus are two in number; and might with propriety have been united with those in the preceding genus. The first is termed C. cærulescens, and is a native of the Molucca isles; and the second, C. equulus, was described by Forskael.

GENUS LXXII. CÆSIOMORUS.

One dorsal fin; no lateral ridge; separate spines in front of the dorsal fin.

This genus is nearly allied to the preceding, and contains 2 species described from the MSS. of Commerson.

GENUS LXXIII. CORIS.

Covering of the head entire; one dorsal fin; the 1st or 2d rays of the ventral fins twice as long as the others.

Naturalists are indebted to Commerson for a knowledge of the two species which compose this genus. These he termed C. aygula and C. angulatus.

GENUS LXXIV. GOMPHOSIS.

Snout produced, in form of a nail; head destitute of scales like those of the back.

Commerson likewise instituted this genus, consisting of two species—the G. cæruleus and G. varius.

GENUS LXXV. NASO.

A horn or protuberance on the snout; two plates or shields on each side of the extremity of the tail; skin shagreened.

Commerson formed this genus, which contains two species, one of which is the Chætodon unicornis of Gmelin, found in the Red Sea by Forskael, and at the Isle of France by Commerson.

GENUS LXXVI. KYPHOSUS.

Back elevated; a hunch on the shoulder; gill lid with scales like the body.

This Commersonian genus contains one species, the K. bigibbus.

GENUS LXXVII. OSPHRONEMUS.

Ventral fins, each of five or six rays, the first spinous, and the second terminated by a long filament.

This genus contains two species. The first of these, O. goramy, is an inhabitant of the fresh waters of Hindostan and China. It has been naturalized in the Isle of France, and ought to be translated to Europe. As food, it is said to be of exquisite flavour. The second is the O. gallus, the Scaurus gallus of Forskael. It frequents the coasts of Arabia, and is considered by the inhabitants as a noxious species.

GENUS LXXVIII. TRICHOPODUS.

Ventral fins with one ray longer than the body; one dorsal fin.

The genus contains two species. One of these is the Labrus trichopterus of Gmelin, a native of the Indian seas. The other is T. mentum, described from a drawing by Commerson.

GENUS LXXIX. MONODACTYLUS.

Ventral fins of one short ray. One dorsal fin.

The M. falciformis was first observed by Commerson, and is the only species of the genus.

GENUS LXXX. PLECTRORINCHUS.

Lips plaited and marginated; one or more of the plaits of the gill-lid denticulated.

La Cepede instituted this genus. The name is from πλεκτρον, *pecten*, and ρυγχος, *rostrum*. There is but one species observed by him in the Dutch collection.

GENUS LXXXI. POGONIAS.

One dorsal fin; chin bearded.

This genus, from πωγων, *barba*, was instituted by La Cepede for the reception of one species, the P. fasciatus, in the collection of the Stadtholder at the Hague.

GENUS LXXXII. BOSTRYCHUS.

Body long; serpentine; two dorsal fins; two tentacula on the upper jaw.

The two species of which the genus consists are but imperfectly known. They rest on the authority of Chinese drawings.

GENUS LXXXIII. BOSTRYCHOIDES.

One dorsal fin. In other respects like the preceding.

A Chinese drawing of the only species of this genus was found in the Dutch collection.

GENUS LXXXIV. ECHENEIS. *Sucking Fish.*

Sucking fish.

Head depressed, and furnished with an organ of adhesion, consisting of an oval plate with transverse folds.

The name of the genus is derived from εχω, *habeo*, and ναυς, *navis*; because the best known species was supposed to have the property of sticking to ships, and retarding their motions. It is the *remora* of the ancients.

GENUS LXXXV. MACROURUS.

Two dorsal fins; tail twice as long as the body.

This genus was instituted by Bloch for the reception of the Coryphæna rupestris of Linnæus, which is found on the coasts of Greenland and Iceland. To the inhabitants of these countries it furnishes a plentiful supply of nourishing food. In some of the districts where it is found it is called berg-lax, or rock salmon. It is the *ingminniset* of the Greenlanders.

GENUS LXXXVI. CORYPHÆNA.

Head truncated, or very obtuse; one dorsal fin, nearly as long as the body and tail.

This genus contains sixteen species, which La Cepede has distributed into sections, from the shape of the tail. The first species which La Cepede describes is the C. *hippurus*, which is found both in the Atlantic and Pacific ocean. Its flesh is very agreeable; and being a voracious fish, easily taken, and fond of following vessels, often furnishes the sailor with a grateful repast. When taken out of the water, the beautiful combinations of colours fade as the fish expires, and the dying coryphene is contemplated by sailors with as much delight as the ancient Romans are said to have exhibited on viewing similar changes in the expiring mullet, when brought to the table before the feast began.

GENUS LXXXVII. HEMIPTERONOTUS.

Head truncated; one dorsal fin, about half the length of body and tail.

La Cepede formed this genus from two species formerly included in the genus Coryphæna. The H. *quinque-maculatus* of La Cepede, the *Coryphæna pentadactyla* of other writers, inhabits the rivers of China, the Molucca isles, and other places in the Indian Archipelago. It is gregarious, appearing in vast shoals, and is eagerly sought after as an article of food. It is dried or salted, and forms an article of trade in those countries similar to the cod fishery of our northern districts.

GENUS LXXXVIII. CORYPHENOIDES.

Head truncated, or very obtuse; one dorsal fin; gill opening a simple transverse slit.

This genus contains only one species, the C. branchiostega. It inhabits the seas of Asia, and differs from the genus Coryphæna principally in the form of the gill opening.

GENUS LXXXIX. ASPIDOPHORUS. *Pogge.*

Pogge.

Body and tail covered with a scaly coat of mail; two fins on the back.

This genus was first instituted by Scopoli, and afterwards adopted by La Cepede for the reception of two species included in the genus Cottus. The first is the *Cottus cataphractus* of Linnæus, common in the European seas; and the second is the C. *japonicus* of Gmelin, which was first described by Pallas as a native of the seas about the Kurile islands. It is destitute of the cirri or beard under the throat, and from that circumstance ought perhaps to be referred to another genus.

GENUS XC. ASPIDOPHOROIDES.

Body and tail armed with a coat of mail; one dorsal fin; rays of the ventral fins fewer than four.

This genus bears a very close resemblance to the preceding, from which it is principally distinguished by the union of the two dorsal fins. The only species it contains is the Cottus monopterygius of Gmelin, a fish which inhabits the coast of Tranquebar.

GENUS XCI. COTTUS. *Bull head.*

Bull-head.

Head larger than the body; form approaching conical; two dorsal fins; spines and tubercles on the head or gill lid; ventral fins with more than three rays.

La Cepede describes nine species, some of which are used as food.

The grunting bull-head, Cottus gruniens, a native of the American and Indian seas, is considered as esculent food. The liver, however, is said to possess noxious qualities. When first taken from the water, this fish utters a sound, in some degree resembling the grunting of a pig, and produced by the sudden expulsion of air from the internal cavities through the gill covers and mouth.

The Cottus insidiator, a native of the Arabian seas, is said to bury itself in the sand, and wait the approach of its prey. When the small fish have approached sufficiently near, it then darts out upon them with considerable velocity. The C. scorpius, which in this country is despised, is eagerly sought after as food by the inhabitants of Greenland. From the liver they likewise extract an oil. This animal is very vivacious. It can close the gill opening so closely, by means of the lid, as to prevent the atmosphere from drying the gills, and consequently obstructing respiration.

GENUS XCII. SCORPÆNA.

Head covered with spines or protuberances; destitute of small scales; one dorsal fin.

The species of this genus, sixteen in number, are distributed into two sections from circumstances connected with the beard. They have all a very uncouth appearance, and they are armed with formidable spines. The S. horrida, says Shaw, resembles rather some imaginary monster of deformity than any regular production of nature. The head is very large, perfectly abrupt in front, and marked by numerous tubercles, depressions, and spines. On the top is a semilunar cavity; the mouth opens from the upper part, and is large, and of a shape resembling a horse shoe. It is a native of the Indian seas. The S. porcus is the most common European species. It is found plentifully in the Mediterranean, where it lurks among the sea weeds, and, as opportunity offers, darts upon its prey. When seized by any stronger animal, it twists itself violently, and, erecting its strong spines, makes a vigorous resistance. Wine, in which this fish was suffered to die, was esteemed by the ancients as a salutary medicine. The S. scrofa, which is found in the Atlantic and Mediterranean, is said to prey not only on the smaller fishes, but on the aquatic birds as they swim on the surface. The S. antennata, remarkable for two long tentacula, surrounded by several fibrous brown bars seated immediately above the eyes, is a native of Amboyna, and its flesh is said to be exquisite. In the S. volitans, the pectoral fins are so large, that the fish can fly for a short distance. It is the Gasterosteus volitans of Linnæus.

GENUS XCIII. SCOMBEROMORUS.

One dorsal fin; spurious fins above and below, in front of the caudal fin; no separate spines in front of the dorsal fin.

The S. plumierii is the only species of the genus, and is a native of Martinique. It was described by La Cepede from the drawings of Plumier.

GENUS XCIV. GASTEROSTEUS. *Stickle-back.*

Stickleback.

One dorsal fin; separate spines in front of the dorsal fin; tail carinated laterally; one or more spinous rays to each ventral fin.

The species of this genus are natives of Europe. The G. aculeatus is common in rivers. It is sometimes found in such plenty as to be employed as manure, an oil excellent for burning may be expressed from the body. The other species are natives of the seas. They are armed with sharp spines on the back, so that few fish venture to seize them.

GENUS XCV. CENTROPODUS.

Two dorsal fins; ventral fins with one spine, and five or six small articulated rays.

This genus, from Κεντϱον, *aculeus*, and πȣς, *pes*, was created by La Cepede for the reception of one species, C. rhombeus, observed by Forskael in the Red Sea.

GENUS XCVI. CENTROGASTER.

Ventral fins with four spines and six articulated rays.

This genus contains two species which inhabit the sea of Japan. They were first described by Houttuyn in the *Act. Haerl.* vol. xx. 2. p. 334. No. 22.

GENUS XCVII. CENTRONOTUS.

One dorsal fin; ventral fins with at least four rays; a longitudinal crest on each side of the tail, and two spines in front of the anal fin.

This genus, formed from Κεντϱον, *aculeus*, and νωτος, *dorsum*, contains eleven species. They are all of a small size. The most remarkable among these is the pilot fish of Willoughby, the C. conductor of La Cepede, which has often excited the astonishment of observers. It follows vessels to feed on the substances thrown overboard; and is generally seen in company with the shark, which in the opinion of some it conducts to its prey.

Pilot fish.

GENUS XCVIII. LEPISACANTHUS.

Scales of the back large, ciliated, and terminated by a spine; the gill lid denticulated behind.

This genus, from Λεπις, *squama*, and ακανθα, *spina*, was instituted by La Cepede. It contains only one species from Japan, first described by Houttuyn.

GENUS XCIX. CEPHALACANTHUS.

Two long denticulated spines on each side of the head behind.

This genus, formed from Κεφαλη, *caput*, and ακανθα, *spina*, was instituted by La Cepede. It contains only one species, the Gasterosteus spinarella of other naturalists. It differs from the Sticklebacks in wanting the spines on the back. It is a small fish, and a native of India.

GENUS C. DACTYLOPTERUS.

One small fin, consisting of rays connected by a membrane near each pectoral fin.

La Cepede formed this genus from δακτυλος, *digitus*, and πτερον, *pinna*, for the reception of two species of fishes formerly included in the genus Trigla. The D. priapoda is one of those fishes capable of flying for a short distance in the atmosphere. Hence it has been termed the sea-swallow, by sailors. It is found principally near the tropics, but is also met with in the Mediterranean. The other species, D. Japonicus, was first described by Houttuyn. It is the Trigla alata of Gmelin.

GENUS CI. PRIONOTUS.

Soft rays near each pectoral fin separate; serrated spines between the dorsal fins.

There is but one species belonging to this genus, a native of the American seas. It is the Trigla volitans minor of Brown. Jamaica, 453. tab. 47. fig. 3.

GENUS CII. TRIGLA. *Gurnard.*

Gurnard.

Soft separate rays near each pectoral fin; no spines in the interval between the dorsal fins.

The name of the genus is from τριγονος, *terpariens*, in reference to the fecundity of the fish. Many of the species have the power of raising themselves into the air, when the sea does not afford them a safe asylum. Their flesh is white and insipid; and is seldom sought after when other fish can be obtained.

GENUS CIII. PERISTEDION.

Soft separate rays near each pectoral fin; one dorsal fin; one or more bony plates on the under side of the body.

This genus was formed by Lacepede, and contains two species. They are readily distinguished from the species of the genus Trigla by the osseous plates, which form a coat of mail on their under side. The P. malarmat of Lacepede, the Trigla cataphracta of Gmelin, is found in the European and Indian seas. It is sought after as food, although its flesh is said to be dry and insipid. It swims with great rapidity, and is very active in all its movements. The P. chabrontera is found in the Mediterranean, and was first described by Osbeck.

GENUS CIV. ISTIOPHORUS.

Two dorsal fins, the first very long elevated and rounded; two rays to each ventral fin.

The T. gladifer is the only known species. It is an inhabitant of the tropical seas, and its appearance is considered by sailors as the presage of a storm. It resembles in many respects the sword-fish. It grows to a great size, swims with great velocity, and possesses undaunted courage. It often strikes its snout against vessels with such force as to break it; and, in consequence of its boldness, proves a dangerous enemy to fishes equal to itself in size. When young, its flesh is considered as agreeable to the taste; but when old, it is oily and indigestible.

GENUS CV. GYMNETRUS.

No anal fin; one dorsal fin; the rays of the ventral fins elongated.

This genus contains only one species, which was instituted by Bloch, the G. Hawkenii, a native of the Indian seas, and occasionally in those of Europe.

GENUS CVI. MULLUS. *Surmullet.*

Surmullet.

Scales large, and easily detached; summit of the head bluntly elevated; under jaw with a beard.

There are fourteen known species in the genus. The most remarkable of these is the Red Surmullet, Mullus barbatus of Linnæus. This fish, when alive, presents some of the most brilliant colours exhibited in nature, and the changes which they experience as the fish expires are singularly various. The luxurious Romans brought this fish alive to table in a glass vessel, and, suffering the fish to expire, contemplated with delight the successive changes of colour. After pleasing the eye by this fine display, the fish was removed and dressed for the feast.

GENUS CVII. APOGON.

Scales large and deciduous; head bluntly raised; no beard on the under jaw.

The generic name is from απωγων, imberbis. The only known species is the A. ruber of La Cepede, the Mullus imberbis of Willoughby. It is found chiefly on the rocky coast of Malta, and differs from the surmullets in wanting the beard or cirrus on the lower lip. It is of a fine red colour; the opening of the mouth is large, and the palate and jaws very rough.

GENUS CVIII. LONCHURUS.

Pectoral and caudal fins equal at least to a fourth of the whole length of the body: dorsal fin long and indented.

Bloch instituted this genus for the reception of a fish brought from Surinam, which he termed L. barbatus. La Cepede changed the trivial name into dianema, instigated apparently by no other feeling than the love of change. The nose or upper lip is produced into an obtuse short snout, so as to cause the mouth to appear as if placed somewhat beneath. The head is covered with scales like those on the back, and the jaws are furnished with small sharp teeth.

GENUS CIX. MACROPODUS.

Ventral fins the length of the body, caudal fin forked, its length equal to a third part of the body: head and gill lid covered with scales similar to the back; opening of the mouth very small.

This genus from μακρος, *longus*, and πους, *pes*, contains only one species, M. viridiauratus, an inhabitant of the fresh water lakes of China, but whose history is little known.

GENUS CX. LABRUS. *Wrasse.*

Wrasse.

Lips thick; upper lip protrusile; no teeth in the form of grinders or incisors; rays of the dorsal fin terminated by a filament.

The name of the genus is expressive of the thick lips with which the species are furnished, and is a term used by Ovid. La Cepede describes 130 species. Some of these, however, rest on very doubtful authority, and a few may be considered as varieties. The characters by which they are separated depend, in a great measure, on the number of the rays of the fins. They are all remarkable for the brilliancy of their colours, the size of their scales, and the strength of their teeth, and we may add, for their extensive distribution. In all the seas of the globe some species belonging to this genus have been found. Few of the species are esteemed as food, and although some are reputed poisonous, the evidence on which the belief rests is unsatisfactory. Many of the species are solitary, while a few appear to be gregarious. The Labrus julis is said to live in vast troops; and, if we may credit Ælian, will attack and bite men bathing in the water. The flesh of the Labrus cinædus is soft, tender, and easy of digestion, and suitable for the young and weak.

GENUS CXI. CHEILINUS.

Lips thick; rays of the dorsal fin terminating in a filament: large scales, with appendages at the base of the caudal fin.

This genus of La Cepede contains two species, viz. C. scarus and C. trilobatus. The first appears to be the true Scarus of the ancients. It inhabits the shores of the Mediterranean, and has been often examined. It is of a whitish colour mixed with red. The scales are large and transparent. This species lives in shoals, and such is the attachment which is said to prevail among them, that according to Appian, when one has taken the bait, another will come to its assistance, and bite the cord to enable it to escape. This fish was eagerly sought after by the luxurious Romans, who preferred the liver, and even the intestines without being emptied. Its food consists of marine plants. The second species is described by La Cepede from the manuscripts of Commerson, and is a native of the Indian seas.

GENUS CXII. CHEILODIPTERUS.

Upper lip extensile, two dorsal fins; no cutting or grinding teeth: gill-lid destitute of spines or processes.

This genus contains ten species, divided into two sections, from the form of the tail. Little more is known of their history than their systematic characters. They were formerly included in the genera Sciæna and Labrus.

GENUS CXIII. OPHICEPHALUS.

Scales of the head polygonal, larger than those of the back; all the rays of the fins jointed.

The name of this genus, from *οφις*, *serpens*, and *κεφαλη*, *caput*, is sufficiently expressive of the distinguishing character of the species. These are two in number, which were described by Bloch, and come from the coast of Coromandel. The scales of these fishes, where exposed, are tuberculated, and feel rough to the touch. They inhabit fresh water lakes and rivers, and feed on aquatic plants. Their flesh is esteemed agreeable and salubrious.

GENUS CXIV. HOLOGYMNOSUS.

Scales invisible; ventral fins resembling a fleshy beard; tail as if formed of two truncated cones, united by their summits.

La Cepede formed this genus, from *ὅλος*, *totus*, and *γυμνος*, *nudus*, for the reception of the H. fasciatus, a native of the equatorial seas, where it was first observed by Commerson.

GENUS CXV. SCARUS.

One dorsal fin; jaws osseous, prominent, occupying the place of teeth.

This genus was instituted by Forskael, and contains at present nineteen species. They are remarkable for the brilliancy of their colours, and the armature of their fins. The mouth in the species of this genus is constructed rather in imitation of some of the cartilaginous fishes, as the Diodon, than of any of the osseous fishes. The jaws are bony, entire in some species, and divided in others, and destitute of true teeth, but often tuberculated or crenulated. They feed on crustaceous and testaceous animals, and likewise on sea weeds. The flesh of the Scarus rivulatus is pleasant to the taste, but the wounds made by the spines of its fins being difficult to heal, it has been considered as venomous. It frequents the coasts of Arabia.

GENUS CXVI. OSTORINCHUS.

Two dorsal fins; osseous jaws prominent, and occupying the place of teeth.

This genus was instituted by La Cepede, and the only species of which it consists (discovered by Commerson) has been named by him in honour of M. Fleurieu. It is a native of the Equatorial seas.

GENUS CXVII. SPARUS. *Gilt-head.*

Gilt-head.

Cutting or grinding teeth in several rows; the height of the body nearly equal to its length.

Forskael formed this genus, deriving the name from *σπαιρειν*, *palpitare*, on account of the rapid motions of the fish when taken from the water. It is a very numerous genus. About a hundred species have been described by ichthyologists. They are distributed into three sections, from characters furnished by the form of the tail. The lunulated gilt-head, Sparus aurata, was well known to the ancients, and by them dedicated to the goddess Venus. In spring, this species frequents the shores, and even enters the mouths of rivers. Its flesh is said to improve in fresh water, and hence Duhamel and others have recommended its being translated into lakes and rivers. As food, it was much prized by the ancients, and valuable medical qualities were ascribed to it. Where common, as in the Mediterranean, it is often salted, and sent inland as an article of trade. Several species have a remarkable phosphorescent property. Willoughby first observed this in the S. pagrus, but it is more remarkable in the S. chrysurus. This last fish inhabits the seas of Brazil, and when a few of them are swimming in company, they emit so much light, that in the darkest night a person might see to read by means of it. This property enables the fish to pursue its prey with more certainty; but, on the other hand, it gives information to its foes. Its flesh is esteemed excellent, and much sought after.

GENUS CXVIII. DIPTERODON.

Two dorsal fins; mouth with several rows of teeth.

This genus contains six species. The D. asper inhabits the rivers of France and Germany; and, being very vivacious, might easily be translated into this country, in the more temperate seasons of the year. Its flesh is esteemed excellent, and in our rivers and lakes would prove a valuable addition to our stock of food. As this fish searches for its food in the mud, in which there are occasionally small pieces of gold, and as these have sometimes been found in its stomach, the fishermen have concluded that its food was gold. The flesh of the D. zingel is equally white, firm, and palatable, and is found in the same situations. It is so bold and vigorous, and so well protected by means of scales, that few fishes will venture to attack it. Hence it multiplies very rapidly.

GENUS CXIX. LUTJANUS.

One dorsal fin; a process to one or more of the pieces of the gill-lid; no spines on these pieces.

This genus contains, according to La Cepede, seventy-four species. The L. anthias is the *ἱερος ἰχθὺς* of the Greeks, who fancied that no dangerous fish could reside in the waters in which it lived, and that divers might descend with safety, if they knew that this fish was an inhabitant of the place. It feeds on small fishes, and is very common in the Mediterranean. The L. johnii, so named by Bloch in honour of his missionary friend John, is found on the coast of Tranquebar. Its flesh is white and palatable. The L. plumierii of La Cepede, the Anthias striatus of Bloch, found in the Atlantic ocean, is also esteemed safe and agreeable food. The Lutjanus scandens, first described in the Linnean Transactions, vol. iii. is remarkable for its power of creeping up the stems of trees, by means of the spinous processes of its fins and gill-lid.

GENUS CXX. CENTROPOMUS. *Basse.*

Basse.

Two dorsal fins; one or more processes to each piece of the gill-lid; no spines on these parts.

La Cepede instituted this genus, which contains twenty-one species. The name is derived from *κεντρον*, *aculeus*, and *πωμα*, *operculum*. The Centropomus sandat of La Cepede, the Perca lucioperca of Linnæus, inhabits the fresh waters of all the countries of the north of Europe It grows to a great size, and its flesh is white, tender, and pleasant to the taste. In the form of its head, and the size of its teeth, it bears a near resemblance to the pike; while, in the structure of its gill-lid, the number and situation of its dorsal fins, and the hardness of its scales, it approaches in appearance the perch. Hence, almost all naturalists have termed it lucioperca. It is a matter of regret that this fish dies so quickly upon being taken out of the water: hence it cannot be transported alive to any distance. But as it is one of those fishes which, if translated into our lakes and rivers, would prove a valuable addition, the fecundated eggs might be employed with ease. In this department of rural economy, how much remains to be done

GENUS CXXI. BODIANUS.

No processes on the gill-lid; plates of the gill-lid spinous; one dorsal fin.

The genus contains twenty-four species. The most remarkable species is the B. palpebratus, first accurately described by Pallas. It has a moveable membranaceous plate above each eye, supposed to assist the animal in regulating the admission of light to that organ. It is a native of Amboyna. The B. pentacanthus, whose trivial name La Cepede, with his wonted love of barbarisms, has changed into jaguar, is a native of the coast of the Brazils. It prefers the mouths of large rivers, near which it grows very fat, and its flesh acquires an increased degree of delicacy and flavour. It is there termed jaguar. The B. aya frequents the lakes of Brazil, and is there salted or dried in the sun as an article of trade. It multiplies very rapidly, and might probably, with little difficulty, be translated to the fresh water lakes of Europe. Its flesh is esteemed good. The B. guttatus of Bloch, changed by La Cepede into B. jacob-evertsen, the name of a Dutch sailor, is found at St Helena, the East Indies, and Japan. It becomes very fat, and is eagerly sought after by Europeans. The B. apua is another of the Brazilian species used as food. Its flesh is oily, and of exquisite flavour.

GENUS CXXII. TŒNIANOTUS.

One or more spines on the gill-lid; dorsal fin very long.

This genus, from *ταινια*, *tenia*, and *νωτος*, *dorsum*, contains only two species, remarkable for their lengthened shape. The first species, T. latovittatus, was observed by Commerson in the Isle of France. He found in its stomach the fragments of corals and of shells. Its teeth are very small, and its tongue and palate destitute of asperities; yet the hardness of its jaws, the number of its teeth, and the continuance of its efforts, enables it to triturate those hard bodies, for the performance of which, in other fishes, more powerful grinders are provided. The second species, T. triacanthus, has the tail rounded, while in the former it is forked. Its habitat is unknown, as it was found preserved in spirits in the Dutch collection, during its captivity in Paris.

GENUS CXXIII. SCIÆNA.

Gill-lid furnished with spines, but destitute of processes; two dorsal fins.

This genus contains eleven species, distributed into sections from the form of the tail. They differ from the genus Bodianus chiefly in the number of the dorsal fins. The *Sciæna coro* is a native of the Brazils, and is taken at all seasons, although its flesh is said to be dry and insipid. The Sciæna umbra, the coracinus of the ancients, is the most important species of the genus, and has been long known. It inhabits the Mediterranean and Adriatic seas, and is found peculiarly abundant in the Nile. It lives in troops, and feeds on crustaceous and testaceous animals. It is esteemed excellent food when in season. Those which are found in fresh water are reckoned preferable to those taken in the sea, and the young are considered as more palatable than the old. The ancients attributed to this fish the most extraordinary medical virtues.

GENUS CXXIV. MICROPTERUS.

Rays of the second dorsal fin short.

This genus contains one species, which La Cepede has named in honour of Dolomieu. We are ignorant of the discoverer and the locality of this species: it was found in the museum at Paris.

GENUS CXXV. HOLOCENTRUS.

One dorsal fin; one or more spines, and a process on each gill-lid.

Bloch formed this genus from species chiefly belonging to the Perca of Linnæus. At present, it contains sixty-five species, divided into sections from characters furnished by the caudal fin. The H. schratzer is found abundantly in the Danube and its tributary streams. Its flesh is white, firm, and salutary, and of a pleasant taste. It feeds on small insects and worms, and spawns in the spring. So valuable a fish ought to be translated to other countries. Although it soon dies when taken from the water, yet with care it may be conveyed to a distance, or the spawn may be used as a substitute.

GENUS CXXVI. PERCA. *Perch.*

Perch.

Two dorsal fins; one or more spines, and a process to the gill-lid; with or without a beard.

This genus, as it now stands, contains fourteen species. The common perch of our lakes may be regarded as the most important species of the genus in an economical point of view. The *P. umbra*, the umbra of the ancients, another valuable species, chiefly resides in the Mediterranean. Its head is compressed and covered with small scales, and it has a thick short cirrus on the lower jaw. Its flesh is firm, but easy to digest, and its head was esteemed a favourite morsel by the ancient Romans. It feeds on sea weeds and small worms. From the skins of some of the species an isinglass is prepared, little inferior to that which is obtained from the air-bag of the sturgeon.

GENUS CXXVII. HARPE.

Many large strong teeth in each jaw: in the upper jaw small compressed teeth in the intervals between the larger ones; dorsal, ventral, and anal fins large and falcated.

This genus was instituted by La Cepede, and contains only one species, H. cæruleo-aureus, of which little is known. It is described from the drawings of Plumier.

GENUS CXXVIII. PIMELEPTERUS.

The whole, or a great part of the dorsal, anal, and caudal fins adipose.

This genus, from *πιμελη*, *pinquedo*, and *πτερον*, *pinna*, contains one species, viz. P. Bosquii, named in honour of M. Bosc, the discoverer. It is found in the Atlantic Ocean, and follows vessels, picking up the fragments of food thrown overboard. It keeps in the eddy at the rudder. It is very difficult to catch, as, with considerable dexterity, it bites off the bait without swallowing the hook. According to Bosc, it is sought after as food by the French, but neglected by the English. In its manners it bears a near resemblance to the pilot fish.

GENUS CXXIX. CHEILIO.

Snout depressed; head and gill-lid destitute of small scales; gill-lid carved; under jaw pendant; dorsal fin low and long, ventral fins small.

This genus, from *χειλος*, *labrum*, contains two species, first observed by Commerson at the Mauritius. The first is termed C. auratus, on account of its golden yellow colour. The lateral line is spotted with black points. The flesh is white, and of a pleasant taste, but disregarded, as it is very common. The second species is termed C. fuscus. The colour is brown, having the ventral fins white, and the dorsal and anal fins spotted with white.

Genus CXXX. Pomatomus.

Gill-lid notched at its upper posterior margin, and covered with scales like those on the back; anal fin adipose.

The P. skib of La Cepede is the only known species. It inhabits the bays and mouths of rivers in Carolina, and is there called skibjack. It performs its motions in a remarkably rapid manner, darting suddenly to a considerable distance. Its flesh is reckoned good. It was observed by Bosc during his residence in the United States.

Genus CXXXI. Leiostomus.

Jaws without teeth, and entirely covered with the lips; the mouth under the snout.

Bosc is the discoverer of L. xanthurus, the only known species, termed in Carolina *yellow-tail*. La Cepede formed the genus from λειος, *lævis*, and στομα, *os*. It differs from the perches in the absence of a process to the gill-lid, and in wanting teeth.

Genus CXXXII. Centrolophus.

A longitudinal crest, and row of distant spines, in part concealed in the skin, above the nape; one dorsal fin.

This genus was instituted by La Cepede to include a fish sent him from Fechamp by M. Noel of Rouen. It was called by the fishermen Le Negre, and hence he has termed the species C. niger. It is of a black colour. The eyes are large, and in front of the dorsal fin there are three spines placed vertically, or pointing forwards.

Genus CXXXIII. Eques.

Two dorsal fins; the rays of the first ending in long filaments; teeth numerous, rigid, and fixed.

The E. Americanus is the only known species of the genus, and has hitherto been found only in the seas of the new continent. It is the Chætodon lanceolatus of Gmelin. In point of brilliancy, and variety, and disposition of colours, this fish has few rivals. The head is small and compressed; the snout rounded. The genus was formed by Bloch.

Genus CXXXIV. Leiognathus.

Jaws without teeth; a strong curved spine on both sides of each of the soft rays of the dorsal fin; a long flattened scaly appendage near each ventral fin; gill-lid carved, and destitute of small scales.

This genus (from λειος, *lævis*, and γναθος, *maxilla*) contains only one species, viz. L. *argenteus*, a native of Tranquebar. It was first described by Bloch under the title Scomber edentulus, but it differs from the mackrel in being destitute of teeth. The head, body, and tail are also compressed, and the opening of the mouth is very small. Its flesh is fat and agreeable to the taste; and being found at all seasons, is of great use to the inhabitants of those shores which it frequents.

Genus CXXXV. Chætodon.

One dorsal fin; gill-lid destitute of processes; teeth small, flexible, and moveable; opening of the mouth small.

This genus has obtained its present name from χαιτη, *seta*, and ὀδους, *dens*. La Cepede has enumerated forty-two species. They chiefly inhabit tropical seas. Their flesh is excellent food, and they are much sought after by sailors. They are remarkable for their form and the brilliancy and variety of their colours. The limits by which the different species are separated are ill defined, so that much confusion prevails in their nomenclature. They all inhabit the seas of tropical countries, and were unknown or disregarded by the ancients. The skeletons of some species have been found along with other ruins of the animal kingdom, in the strata at Mount Bolca. La Cepede particularly mentions the remains of the Chætodon vespertilio and teira. The Ch. marginatus appears to prefer the mouths of rivers, is very common at the Antilles, and its flesh is good. The flesh of the Ch. macrolepidotus, a native of the East Indies, is said, in point of delicacy, to resemble the sole. But the most extraordinary species is the Ch. rostratus, a native of the fresh waters of India. Dr Shaw, after informing us that its prey consists of the smaller kinds of insects, says, "When it observes one of these, either hovering over the water, or seated on some aquatic plant, it shoots against it from its tubular snout a drop of water, with so sure an aim as generally to lay it dead, or at least stupified on the surface. In shooting at a sitting insect, it is commonly observed to approach within the distance of from six to four feet before it explodes the water. When kept in a state of confinement in a large vessel of water, it is said to afford high entertainment by its dexterity in this exercise; since, if a fly, or other insect, be fastened to the edge of the vessel, the fish immediately perceives it, and continues to shoot at it with such admirable skill as very rarely to miss the mark."

Genus CXXXVI. Acanthinion.

One dorsal fin; teeth small, flexible, and moveable; two or more naked spines in front of the dorsal fins.

The three species, of which this genus consists, were formerly included in the genus Chætodon; but the spines, placed behind the head, form a sufficient mark of distinction, and is expressed in the name of the genus from ακανθα, *spina*, and ινιον, *occiput*. The first species, A. rhomboides, is a native of the American seas, as is also the A. glaucus. The flesh of the last species is white and nourishing, and sought after as food. It sometimes grows to the length of 18 inches. The third species inhabits the rocky shores of Arabia, where it was observed by Forskael. It has something of the habit of a flounder, and seldom exceeds a foot in length.

Genus CXXXVII. Chætodipterus.

Body and tail compressed; two dorsal fins; teeth small, flexible and moveable; gill-lid destitute of processes and spines.

La Cepede instituted this genus for the reception of C. Plumierii. This species is nearly as deep as it is long, and its sides are lozenge shaped. The general colour is green, mixed with yellow, crossed by six narrow bands of deep green. It was observed in the West Indies by Plumier; and prefers a stony bottom.

Genus CXXXVIII. Pomacentrus.

One dorsal fin; gill-lid furnished with a process, but destitute of long spines; teeth small, flexible and moveable.

This genus contains seven species. They inhabit the seas of warmer countries, and in general exhibit a fine display of colours. One species has indeed obtained the name of Peacock, (P. pavo,) from the variety and lustre of its colours. It is a native of the Indian seas, and was first described by Bloch.

Genus CXXXIX. Pomadysis.

Two dorsal fins; teeth small, flexible and moveable; gill-lid furnished with a process.

Forskael discovered, in the Arabian sea, the only species of the genus termed P. argenteus, with whose habits we are still unacquainted.

Genus CXL. Pomacanthus.

One dorsal fin; teeth small, flexible, and moveable; gill lid furnished with long spines, but no process.

The seven species included under this head, were formerly arranged in the genus Chætodon. The Pe. canescens, a native of Arabia, and first described by

Forskael, is sought after as food, and its flesh is agreeable. The P. paru, a native of the American seas, is likewise much sought after as food, and is taken by the hook.

GENUS CXLI. HOLACANTHUS.

One dorsal fin; teeth small, flexible, and moveable; gill lid with a process and spines.

This genus contains thirteen species. They inhabit the tropical seas, and are elegantly ornamented with curved coloured bands. The species are divided into sections from circumstances connected with the tail. The Holacanthus imperator is not only remarkable on account of the brightness and distribution of its colours, but of its excellence as food. It is an inhabitant of the Indian ocean, and its flesh is remarkably fat and palatable, reckoned equal in point of flavour and richness to the salmon. It is considered as superior to any other fish known in that vast ocean. It grows to about a foot in length, and is of an oval shape.

GENUS CXLII. ENOPLOSUS.

Two dorsal fins, teeth small, flexible, and moveable; a process and one or more spines on the gill lid.

This genus, from ενοπλος, *armatus*, was instituted by La Cepede, and includes only one species, named Whitii in honour of the discoverer. See White's *Tour, New South Wales*, p. 254. tab. 39. It was at first termed Chætodon albescens. Its colour is white, tinged with blue, and silvery.

GENUS CXLIII. GLYPHISODON.

One dorsal fin; body and tail compressed; teeth indented or carved.

This genus, formed from γλυφις, *incisura*, and οδους, *a tooth*, contains two species. The G. moucharra of La Cepede, Chætodon saxatilis of Bloch, is found on the coast of Arabia, as well as on the shores of the Brasils. It remains always in deep water, among corals, on the polypi of which it subsists. Although its flesh is white, yet it is dry and insipid. The flesh of the other species G. kakaitul of La Cepede, the Chætodon maculatus of Bloch, a native of the fresh waters of Surinam and Coromandel, is so full of bones, that none but the negroes make use of it.

GENUS CXLIV. ACANTHURUS.

One dorsal fin; body and tail compressed; one or more spines on each side of the tail.

The name of the genus is derived from ακανθα, *spina*, and ουρα, *cauda*. There are six species, the most remarkable of which is the A. chirurgus or Lancet fish, so called from the wounds which it inflicts with its caudal spines, being deep, and accompanied with a flow of blood. It is found in the sea at the Antilles, where it is much sought after for dietetical uses. The A. nigricans is found in the warmer seas of both continents. It feeds on small crabs and shells, and its flesh is firm and palatable.

GENUS CXLV. ASPISURUS.

One dorsal fin; body and tail compressed; a hard shield-like plate on each side of the tail.

This genus, from ασπις, *clypeus*, and ουρα, *cauda*, contains only one species, vis. A. sohar. It was first described by Forskael, who found it in the Arabian gulf. It lives on the remains of organised bodies, and resides near the shore.

GENUS CXLVI. ACANTHOPODUS.

One dorsal fin; one or two spines in the place of each ventral fin.

This genus contains the chætodon argenteus and Bodaertii of Gmelin, of whose history little is known.

GENUS CXLVII. SELENE.

Two dorsal fins, with spines in the space between them.

This genus, from σεληνη, *luna*, contains two species, natives of the West Indies and America. The first termed S. argentea, was described by La Cepede from the drawings of Plumier; and from its shape is termed by the natives moonfish. The second S. quadrangulatus, is the Faber marinus fere quadratus of Sloane, and placed in the genus zeus by many naturalists. In shape it is almost square.

GENUS CXLVIII. ARGYREIOSUS.

One dorsal fin, with spines in front.

The zeus vomer of Linnæus is the only species of this genus. It is common to the coast of Norway and the Brazils. This is a very remarkable circumstance, indicating a constitution capable of supporting opposite extremes of temperature. In whatever situation it is found, it presents the same form, and exhibits the same beauty of colouring. It arrives at the same size in the seas of both continents, and in both its flesh is esteemed as excellent. The name of the genus is derived from αργυρεος, *argenteus*.

GENUS CXLIX. ZEUS. *Doree.*

Doree.

One dorsal fin, without spines in front, the rays terminating in long filaments.

This genus, as now restricted, contains only three species. The first of these is the Z. ciliaris, so named from a few of the last rays of the dorsal and anal fins extending like hairs far beyond the connecting membrane, and even farther than the tail itself. La Cepede, in the absence of observation, hazards the conjecture, that the animal may use these long filaments to entice its prey to approach, as a few fishes are known to do, who possess long filaments. He even supposes, that by means of these, twisted round aquatic plants, the fish maintains itself stationary for particular purposes. These conjectures are supposed to be rendered probable from the facts which are established with regard to the cunning of another species, the Z. insidiator, which like the chætodon rostratus, ejects water through its tubular mouth on flies that alight on aquatic plants, and thus stupifies and secures them; but the analogy is here very remote, as the points of resemblance are so few. The flesh of this last species is rich and agreeable; a hook baited with a fly is employed in taking it. Both species are natives of the Indian seas. The third species is the Z. faber, or common doree. It is a native of the Northern Atlantic and Mediterranean seas, and was well known to the ancients.

GENUS CL. GALLUS.

Two dorsal fins, without spines between them.

La Cepede formed this genus for the reception of the Zeus gallus of other writers. This species is very widely distributed, being common to Greenland, the Mediterranean, South America, and the East and West Indies. Its flesh is esteemed good. It feeds on small worms and fishes.

GENUS CLI. CHRYSOTOSUS. *Opah.*

Opah.

One dorsal fin; jaws destitute of teeth; body and tail compressed; height equal to the length.

The generic name is from χρυσωτης, *aurator*. The Zeus luna of Linnæus is the only species. It is found in the Northern and Atlantic seas, and from the inspection of drawings in the Museum at Paris, Lacepede is disposed to consider that it likewise inhabits the Chinese seas. Dr Mortimer says, that the Prince of Anamaboe, on the coast of Africa, recognised, in an English specimen, a fish which he said was common on his own shores, and very good to eat.

GENUS CLII. CAPROS.

Body and tail compressed; jaws destitute of teeth; two dorsal fins.

This genus, from *καπρος*, *aper*, was instituted by La Cepede, and so named from the resemblance the only known species bears to a wild boar. It is the Zeus aper of Linnæus, and has long been known as an inhabitant of the Mediterranean. It is scarcely three inches in length, and is of a reddish colour; the snout is somewhat produced and sharpish, and protrudes in the act of opening like the common Doree. Its flesh is said to be very coarse, and of a rank flavour.

GENUS CLIII. PLEURONECTES. *Flounder.*

Flounder.

With pectoral fins; both eyes on the same side of the head.

This extensive and important genus, containing upwards of forty species, derives its name from *πλευρον*, *latus*, and *νηκτης*, *natator*. The genus is divided into two sections, from the position of the eyes, both of which are always placed on one side of the head. In the first division are placed those having the eyes on the right side, and in the second those having the eyes on the left. It sometimes happens, however, that a species with eyes in general on the right side, has been found having its eyes on the left, all the other characters of a species remaining fixed. This circumstance points out the propriety of being cautious in relying on the character furnished by the position of the eyes.

The genus contains at present upwards of thirty species, but a more attentive examination of their characters, than has hitherto taken place, would perhaps point out the propriety of suppressing a few as varieties, and some as hybrids. Their flesh is white, pleasant, and easily digested; and as the species are of considerable size, they are much sought after as food. Several species delight to reside at the mouths of rivers, and even to live in the fresh water. By a little attention these might be translated into lakes and ponds, and thus not only the quantity, but the variety of food furnished might be increased. All the species prefer a sandy bottom, and they are much more numerous in cold than in hot countries.

GENUS CLIV. ACHIRUS.

Both eyes on the same side of the head; no pectoral fins.

This genus, from *α* privative and *χειρ*, *manus*, was formed for the reception of those species which have no pectoral fins, formerly included in the genus pleuronectes. There are six species known. The A. marmoratus inhabits the sea at the Isle of France, where it was observed by Commerson. Its flesh is esteemed excellent. We may observe, that Commerson observed a row of pores at the base of the dorsal and anal fins, equal in number to the rays in those fins, which upon being pressed poured out a milky mucus.

ORDER XX. ABDOMINAL.

GENUS CLV. CIRRHITUS.

Gill-flap of seven rays, the last remote; beards united by a membrane, and placed near the pectoral fins.

This genus contains only one species described from the MSS. of Commerson. It bears a close resemblance to the species of the genus Holocentrus and Perca. The seven filaments of the beard are long, and united by a membrane, resembling a second pectoral fin. There is no mention made of the place where it was found.

GENUS CLVI. CHEILODACTYLUS.

Body and tail compressed; upper lip double and extensile; head abrupt.

There is only one species belonging to this genus, from the East Indies; and described from a specimen in the Dutch collection.

GENUS CLVII. COBITIS. *Loche.*

Loche.

Head, body, and tail cylindrical; eyes near the summit of the head; no teeth; bearded; one dorsal fin; scales minute.

This genus contains three species, two of which have been long known to naturalists. The first, *G. barbatula*, or common Loch, is common in the waters of the southern and middle districts of Europe. It prefers rivers which have a gentle current, to those which are either rapid or dormant. Its flesh, during autumn and spring, is esteemed a great delicacy, superior indeed to all other fresh water fish, especially when it is killed in wine or in milk. It has been translated into some of the northern countries of Europe. It soon expires when removed from the water, and even when placed in water in a state of rest. The *G. tænia* differs in external character from the last, chiefly in having a double spine on each side of the head, a little before the eyes. When taken from the water, it emits a grunting sound like the gurnard, and is more vivacious than the last. Its flesh is dry and insipid. The G. *Tricirrhata* was observed by M. Noel in the rivulets near Rouen. Its beard consists of three filaments.

GENUS CLVIII. MISGURNUS.

Body and tail cylindrical; one short dorsal fin; jaws with teeth.

The *Cobitis fossilis* of Linnæus is the only known species of the genus. It inhabits marshes and lakes with a muddy bottom. It is remarkably vivacious, and is capable of surviving among mud, provided it be moist. This is a wise provision of nature, by which this animal is fitted for those situations in which it resides. When the pools or ditches in which it lives dry up, this animal buries itself in the mud, and lives securely until the rain replenishes its pond. As it is frequently dug up in this situation, it has been supposed to search for its food in the ground like an earth-worm. It will remain alive under ice, provided there is a small portion of unfrozen water around it. It appears to be extremely sensible to the changes in the state of the atmosphere. During calm weather, it remains at rest on the mud in the bottom of the ditch; but, at the approach of a storm, or change of weather, it rises to the surface of the water, and moves about with seeming uneasiness. Hence it is often kept in vessels within doors by the curious, for the purpose of predicting the changes in the weather. In winter, it buries itself in the mud, and issues forth in spring when it spawns. It is found in the marshes and lakes of the midland parts of Europe. Its flesh is soft, and but little sought after.

GENUS CLIX. ANABLEPS.

Pupil of the eye double.

The A. surinamensis, the only known species, was the cobitis anableps of Linnæus. It is a native of the rivers of Surinam, near the sea coasts. We have already adverted to the extraordinary structure of the eyes in this fish, which appear as if furnished with two pupils. The anal fin in the male is composed of nine rays, the last three or four only being distinct. The preceding ones, are in part united with a hollow conical appendix covered with scales, and open at the apex. This opening communicates with the milt and the blad-

Classification of Fishes.

der of urine, and is the passage through which they escape. The species is ovoviviparous.

Genus CLX. Fundulus.

Body and tail nearly cylindrical; jaws with teeth; no beard; one dorsal fin.

There are two species in this genus; the first of these is the *cobitis heteroclita* of Linnæus, whose trivial name is now changed by La Cepede into *F. mud-fish!* It was observed in Carolina by Dr Garden, and was there named mud-fish. The other species inhabits Japan, and was first described by Houttuyn in Act. Haarl. xx. 2. p. 337. n. 26. In the former species there are six rays in each of the ventral fins; in the latter, eight rays.

Genus CLXI. Colubrina.

Head lengthened; above covered with scales, like those of a serpent; no dorsal fin.

This genus has been constructed for the reception of a species whose existence rests on the authority of a Chinese drawing in the Dutch collection. La Cepede has termed it C. Chinensis.

Genus CLXII. Amia.

Head covered with plates, divided by sutures; teeth in the jaws and palate; beard on the upper jaw.

The A. calva, the only known species, is a native of Carolina. It is a fresh water fish, and was originally described by Linnæus from specimens sent him by Dr Garden. It does not appear to have fallen under the inspection of any other ichthyologist.

Genus CLXIII. Butyrinus.

Head without scales, and one fourth of the whole length of the animal; one dorsal fin.

The B. bananus is the only species, of which little satisfactory has been ascertained. It is described by La Cepede from the MS. of Commerson. The tail is forked; on each side of the back there are four longitudinal waved lines, and the lateral line is nearly straight.

Genus CLXIV. Tripteronotus.

Three dorsal fins, and one anal fin.

The hautin of Rondeletius; the T. hautin of La Cepede is the only known species. It is the only fish of this order which possesses three dorsal fins; and, what is more extraordinary, when the number of the dorsal fins is considered, it has only one anal fin.

Genus CLXV. Ompok.

Jaws with a beard and teeth; no dorsal fin; anal fin long.

The only known species of this genus is the O. siluroides. A specimen of this fish was found in the Dutch collection, having the provincial name *Ompok* attached to it.

Genus CLXVI. Silurus.

Head large, depressed; mouth terminal, bearded; one short dorsal fin.

This genus, formerly very extensive, contains at present only eleven species. They are distributed into two sections, from the form of the tail. The *S. glanis*, or common silure, is one of the largest of the inhabitants of the fresh waters. It grows sometimes to the length of 15 feet, and to the weight of 300 pounds. The head is depressed; the snout rounded in front; the lower jaw is longest. There are two filaments on the upper jaw, and four on the under. The general colour is green mixed with black. The eyes are remarkably small. It inhabits the larger rivers of Europe, Asia, and Africa, and is seldom found in the open sea. Its motions are all slow. It lurks under some root with its body sunk in part in the mud; and, by moving the filaments of its beard, it entices the small fishes to approach, when it seizes them. The flesh is white, fat, and pleasant to the taste, but very difficult to digest. The air-bag furnishes isinglass, which is considered excellent. The skin dried and rubbed with oil, is sometimes used as a substitute for glass. This species might be translated with ease into this country; and there appears to be several favourable situations for its growth. The *S. fossilis*, which is a native of the East Indies, is sometimes dug out of the mud like the Misgurnus, which it appears to resemble in habit.

Classification of Fishes.

Genus CLXVII. Macropteronotus.

Dorsal fin very long.

The species of this genus, four in number, were separated by La Cepede from the Siluri, from which they differ in the greater length of the dorsal fin. If such a character be admitted as sufficient to constitute a genus, we fear that the science of ichthyology will speedily revert to that state of confusion and uncertainty which prevailed in the days of Aristotle and Pliny. The first species is the *Silurus anguillaris* of Linnæus, which La Cepede now names M. charmuth. Geofroy, according to La Cepede, has discovered a cavity connected with the gills, which the animal has the power of closing. In this cavity there is a flat cartilaginous substance, divided into many branches, having the surface covered with numerous ramifications of blood-vessels. This organ he considers as a supplementary gill, and is disposed to believe that the circulating system is performed by means of three separate ventricles. But from the details which we have seen, it is impossible to form any distinct conception of such an arrangement. This species is common in the Nile. The *M. batrachus* is a native of Asia and Africa. The skin is so transparent on the sides, that the divisions of the muscles can be perceived like so many transverse lines. The remaining species of the genus, viz. M. fuscus and hexacicinnus are described on the authority of Chinese drawings in the Library of the Museum at Paris.

Genus CLXVIII. Malapterurus.

Dorsal fin adipose, and placed near the tail; furnished with electrical organs.

The Silurus electricus of Linnæus is the only known species of the genus. It has been long known as possessing those benumbing qualities which are so remarkable in the Torpedo. It is found in many of the African rivers. See the article Electricity.

Genus CLXIX. Pimelodes.

Two dorsal fins; the second adipose.

This genus contains twenty-four species, formerly included in the genus Silurus. They are divided into two sections from the form of the tail. The P. bagre is a native of the great rivers on the American continent. There are four filaments in the beard, two orifices to each of the nostrils, and a lengthened cavity on the head. The flesh is held in little estimation. The P. ascita exhibits one of the most remarkable examples of reproduction in the whole system. The eggs, while still in the uterus, gradually increase in size, and distend the skin of the belly until it burst longitudinally. To this slit, the farthest advanced egg approaches, and its integuments give way, opposite to the head of the animal. The embryo is left, resting on the yolk, and attached to it by a cord of vessels. When all the yolk is absorbed, the remains of the egg pass through the slit, and the animal, separated from its mother, begins to enjoy an independent existence. Other eggs come forward to the same position; and when all have been excluded, the edges of the opening meet, and speedily grow together, when a fresh rupture takes place in the following season. This is a curious instance of the ovoviviparous mode of reproduction. This species is found both in the East and West Indies.

Genus CLXX. Doras.

Two dorsal fins; the second adipose; longitudinal rows of large hard plates on the sides of the body.

Two species; viz. D. carinatus and costatus belong to this genus. They were formerly considered as Siluri. The first of these is a native of Surinam; the second is common to America and India. Its flesh is said to have a very unpleasant taste; and the formidable spines with which it is armed, are considered by the fishermen as venomous. For the purpose of curing the wounds which they receive by accident from this fish, they anoint them with the oil which they obtain from its liver, a balm which they frequently carry about with them.

Genus CLXXI. Pogonathus.

Dorsal fins two in number, supported by rays; body with lateral plates.

This genus differs from the former, in the second dorsal fin being radiated. It contains two species, first observed by Commerson. The first named *P. courbina*, a native of Plate river, has twenty-four filaments in the beard of the under jaw. It grows to the length of more than two feet, and weighs upwards of six pounds, but its flesh is soft and insipid. The *P. auratus* has only one filament in the beard on the under jaw.

Genus CLXXII. Cataphractus.

Two dorsal fins; the second with one ray; body with lateral plates.

We owe this genus to Bloch. It contains three species. The first of these, named C. callichthys, is found both in the East and West Indies. It lives in limpid running fresh water, and is said to creep out of the water to a considerable distance from the rivers, and to dig holes in the ground, in which it conceals itself. It seldom exceeds a foot in length. Its flesh is said to be palatable. It has four filaments in the beard, and the tail is rounded. The C. *Americanus* has six filaments in the beard, and has hitherto been observed only in Carolina. The C. *punctatus* has four filaments in the beard, and the tail is in the form of a crescent. It is found in the rivers of Surinam.

Genus CLXXIII. Plotosus.

Two dorsal fins; the second of these, and the anal fin, united with the caudal.

The P. *anguillaris* is the only known species, and is a native of the Indian seas. It was inserted by Bloch in his genus *Platystachus*.

Genus CLXXIV. Ageneiosus.

Two dorsal fins; the second adipose; chin beardless.

The two species, A. armatus and inermis, are natives of the Indian and South American seas, and were formerly included among the Siluri. The first of these has a remarkable long serrated bony process on each side of the head near the nostrils.

Genus CLXXV. Macromphosus.

Mouth beardless; first ray of the first dorsal fin lengthened; strong and notched; second dorsal fin supported by rays.

The Silurus cornutus of Gmelin, is the only known species of the genus. It was first described by Forskael. The snout is about half the length of the body, compressed, and a little recurved at the top. The first ray of the first dorsal fin is serrated beneath for about half its length, and extends nearly to the tail. This fin contains nine rays, the second dorsal fin contains only six.

Genus CLXXVI. Cenrtanodon.

Head depressed, and covered with large hard plates; mouth at the extremity of the snout, without teeth or beard; one or more spines on each gill lid.

This genus contains only one species, formerly termed Silurus imberbis. It was first described by Houttuyn, and is a native of Japan. The body and tail are lengthened, and covered with distinct scales. The eyes are large and approaching.

Genus CLXXVII. Loricaria.

Body covered with a coat of mail; mouth inferior; lips extensile; one dorsal fin.

The genus contains two species, viz. L. setifera, and maculata, natives of the American seas. The mouth of the first is surrounded by a number of small filaments, which are not observable on the latter. These fish bear a very close resemblance to the sturgeon in the armature of the body, the position of the mouth, and the great size to which they attain.

Genus CLXXVIII. Hypostomus.

Body covered with a coat of mail; mouth inferior; lips extensile; two dorsal fins.

The presence of the second dorsal fin, is the character by which this genus is distinguished from the preceding. The only known species is the H. guacari of Lacepede, a native of the American rivers. It is the Loricaria plecostomus of Linnæus. The flesh is said to be good.

Genus CLXXIX. Corydoras.

Body and tail covered on the sides with large plates; mouth terminal; no beard: two dorsal fins, with more than one ray in each.

A specimen of the C. Geoffroy, the only known species, was found in the Dutch collection. Its native country is unknown. In the first dorsal fin, there are two spinous and nine articulated rays. The tail is forked.

Genus CLXXX. Tachysurus.

Mouth terminal, bearded; the first ray of the dorsal and pectoral fins strong; dorsal fins two, radiated.

The existence of the T. sinensis, the only known species, rests on the authority of a Chinese drawing in the Dutch collection.

Genus CLXXXI. Salmo. *Salmon.*

Salmon.

Mouth terminal; head compressd; second dorsal fin adipose; first dorsal fin as near the head as the ventral fins; upwards of four rays in the gill-flap; teeth strong and numerous.

The characters of the twenty-nine species which compose this important and extensive genus, have not been satisfactorily determined. Naturalists, in general, attending to the characters furnished by colour and by the number of rays in the fins, have, we fear, multiplied the species unnecessarily. At present, indeed, it is difficult from the characters in ordinary use, to determine the young animals as of the same species with the old. Recourse must be had to the characters furnished by the organs of respiration, and the intestines; and under the guidance of the marks which they furnish, the species may be satisfactorily determined.

All the species of this genus are elegant in their form, finely variegated in colour, and rapid in their movements. Their flesh is excellent. This in some changes to a fine red upon boiling, in others it continues white.

GENUS CLXXXII. OSMERUS. *Smelt.*

Smelt.

First dorsal fin farther removed from the head than the ventral fins.

The character by which this genus is distinguished from the preceding is so unimportant, that we are at a loss to account for the older naturalists being disposed to separate them. The genus contains six species. The O. eperlanus, or common smelt, is well known. The other species are natives of warmer countries.

GENUS CLXXXIII. COREGONUS.

Teeth in the jaws none, or very small.

Twenty species are described by La Cepede. They were included by Linnæus in the genus Salmo. The C. *lavaretus*, or gwiniad, is sought after on account of its flesh, which is white and tender. They die very soon after they are taken, and hence it is very difficult to translate them. The C. thymallus, or grayling, is likewise another species sought after as food. Its flesh is firm, white, and pleasant to the taste, but considered as difficult to digest. The eggs, or spawn of the C. migratorius, are eaten in Siberia, its native country. The C. Wartmanni, a native of the Swedish lakes, is either eaten in a fresh state, when it is considered as excellent, or salted and carried to a distance. At the age of three years, it is sometimes seized with a distemper which gives it a red colour.

GENUS CLXXXIV. CHARACINUS.

Gill-flap consisting of four rays, or more.

Generic characters, so vague and trivial as those by which the three preceding genera are distinguished, indicate the imperfect state of the science. Sixteen species are described by La Cepede. The first of these is the C piabucu, so named from its provincial name in Brazil, although termed by Gmelin and others argentinus. It is a native of the middle parts of America, inhabiting rivers. It is easily taken with a hook. Its flesh is white and palatable The C. bimaculatus, found in the rivers of Amboyna and Surinam, is likewise remarkable for the whiteness and delicacy of its flesh. All the species indeed bear so close a resemblance to the salmon, that they might have continued under the same genus, and in a separate section, with advantage to the student.

GENUS CLXXXV. SERRASALMUS.

Under part of the belly carinated, and notched like a saw.

The S. rhombeus is the only known species. It is a native of the rivers of Surinam, and was first described by Pallas. It is said to attain to a considerable size. In shape it bears some resemblance to the Chætodons. It is said to be very voracious, and that it will attack ducks which happen to be swimming on the water Its flesh is white, firm, and fat, and held in great estimation. The fish is of a reddish tinge with black points; the sides are silvery, and the fins grey.

GENUS CLXXXVI. ELOPS.

Gill flap of thirty rays or more; eyes approaching; one dorsal fin; a scaly appendage near each ventral fin.

The Saurus maximus of Sloane, now Elops saurus, is the only known species. It is found in Jamaica, where it is called the Sein Fish, or Sea Gally Wasp. In its general appearance, it approaches the common pike. The tail is much forked, and armed both above and below by a strong spine, forming a first or spiny ray on each side of the tail. In the specimen examined by Bloch, no spinous ray in the caudal fin could be perceived. Dr Shaw, however, observed it in a fine specimen preserved in the British Museum.

GENUS CLXXXVII. MEGALOPS.

Eyes large; gill-flap of at least twenty-four rays.

The M. *filamentosus*, brought from Madagascar by Commerson, is the only species yet discovered. The rays in the gill-flap are singularly numerous. The last ray of the dorsal fin extends backwards in the form of a long filament. The species bears a near resemblance to the preceding.

GENUS CLXXXVIII. NOTACANTHUS.

Body and tail lengthened; the nape raised, and anal and caudal fins united; spines in place of a dorsal fin.

The Acanthonotus of Bloch, is the only known species. It grows to nearly three feet in length. It is a native of the East Indies, and is said to be remarkably active in all its motions, and exceedingly voracious.

GENUS CLXXXIX. ESOX PIKE.

Pike.

Opening of the mouth large; jaws with strong teeth; snout depressed; dorsal and anal fins short, nearly equidistant from the head.

This genus contains nine species, which are divided according to the form of the tail into two sections. The common pike, E. lucius, now common in the lakes and rivers of Europe, is a strong active voracious fish, and is not unfrequently compared to a shark. It preys indiscriminately on young fish, serpents, frogs, and the young of aquatic birds. Its flesh is held in some estimation, and is used either fresh, salted, or smoked. The eggs or spawn are formed into a sort of caviar, which is not considered as wholesome. When castrated, pikes are said to become speedily fat. The *E. belone*, or gar-fish, is an inhabitant of the sea, and approaches the shore to spawn. It is considered as the forerunner of the mackrel. The bones become green on being boiled. The flesh is dry and insipid. The E. gladius, which is common to the shores of Asia and America, furnishes a pleasant and wholesome food, and is easily obtained. It multiplies very rapidly.

GENUS CXC. SYNODUS.

Dorsal and ventral fins nearly equidistant from the head; body and tail lengthened and compressed.

This genus contains five species, distributed into two sections, from the form of the tail. The only species of importance in an economical point of view, is the S. Malabaricus. It was inserted in the genus Esox by Bloch. It lives in the rivers on the coast of Malabar. Its flesh is white and palatable.

GENUS CXCI. SPHYRÆNA.

Two dorsal fins; opening of the mouth large.

The number of the dorsal fins furnishes a very obvious character, by which this genus may be distinguished from Esox, with which it was formerly united. Five species are described by La Cepede. The first of these, termed by him *S. spet*, the *Esox sphyræna* of Linnæus, has been known to naturalists since the days of Aristotle. It is found in the Mediterranean sea, and likewise in the Atlantic ocean. The flesh is white, easy to digest, and resembles in flavour the cod. It grows to upwards of two feet in length. The remaining species are new, and described from the drawings of Plumier.

GENUS CXCII. LEPISOSTEUS. *Garfish.*

Garfish.

Body covered with osseous scales; one dorsal fin, more distant from the head than the ventral fins.

The armature of the species of this genus resembles a coat of mail, so hard are the scales, and so closely attached to the body. The L. gavial of La Cepede is the *Esox osseus* of Linnæus. It is a native of the lakes and rivers of Europe, Asia, and America, but in the former country it is rare. The flesh is firm, white, and well flavoured, and much sought after.

Genus CXLIII. Polypterus.

Gill-flap of one ray; two blow holes; dorsal fins numerous.

The P. bichir, the only known species, exhibits many singular peculiarities of structure. It is found in the Nile, and was described for the first time by Geoffroy, in the *Bulletin des Sciences*, No. 61. The body is nearly cylindrical, long, and serpentiniform; in the anal fin are fifteen rays; the tail is rounded. It is known to the Egyptians by the name of *bichir*, and is considered as a very rare animal. It is supposed in general to inhabit the depths of the Nile, remaining among the soft mud, which it is thought to quit only at some particular seasons, and is sometimes taken in the fishermen's nets at the time of the decrease of the river. It is said to be one of the best of the Nilotic fishes, having a white or savoury flesh; and as it is hardly possible to open the skin with a knife, the fish is first boiled, and the skin afterwards drawn off whole.

Genus CXCIV. Scomberesox. *Saury.*

Saury.

Jaws long; dorsal fin immediately above the anal fin; between the caudal fin and the dorsal and anal fins a number of spurious fins, as in the mackrel.

This genus, instituted by La Cepede, contains only one species, with whose history he seems to be very imperfectly acquainted. It is the Saury pike of the British Zoology.

Genus CXCV. Fistularia.

Jaws long, tubular; mouth terminal; one dorsal fin.

The F. petimba of La Cepede is the only known species. It is the F. tabacaria of Linnæus. It was first described by Marcgrave in his history of the Brazils, under the name of Petimbuaba. The tail is perhaps of the most singular construction of any species in the system. It is deeply forked, and from the middle of the furcature springs a very long and thickish bristle or process of a substance resembling that of whalebone, and gradually tapering to a fine point. A variety has been observed by Dr Bloch, in which this part was double, and the snout serrated on each side. This species inhabits the equatorial seas, lives chiefly on the smaller fishes, and its flesh is poor, and unpleasant to the taste.

Genus CXCVI. Aulostomus.

Jaws long, tubular; mouth terminal; longitudinal row of spines instead of the first dorsal fin.

The Fistularia chinensis of Gmelin is the only known species. It is a native of the equatorial sea. It feeds on small worms, and the spawn of fishes. Its flesh is said to be dry and insipid. M. Gazola supposes, that he has observed the remains of this fish in the strata of Mount Bolca.

Genus CXCVII. Solenostomus.

Jaws long and tubular; mouth terminal; two dorsal fins.

The Fistularia paradoxa of Pallas, is the only known species. It is a native of Amboyna, and in its general form appears to bear a close resemblance to the Syngnathi, or Pipe-fish.

Genus CXCVIII. Argentina. *Argentine.*

Fewer than thirty rays to the gill membrane; more than nine rays in each ventral fin; one dorsal fin; colour silvery.

Argentine.

La Cepede describes four species. The first of these, A. sphyræna, or Pearly argentine, is found in the Mediterranean Sea, and in the Atlantic Ocean. The skin of the air bag of this little fish is covered with a silvery powder, or rather shining silvery scales. These are carefully collected and introduced into small globules of glass, to the inside of which they are fastened with gum. These beads are termed artificial pearls, and are used as articles of dress. The A. glossodonta of Gmelin, changed by La Cepede into A. *bonuk*, was first described by Forskael as a native of the Red Sea, where he likewise found the A. *machnata*. The A. *Carolina*, so named from the country in which it has been found, is about the size of a small herring, and lives in the fresh waters.

Genus CXCIX. Atherina. *Atherine.*

Atherine.

Gill flap and ventral fins, with fewer than eight rays; no teeth in the palate; two dorsal fins; a longitudinal silvery band on each side.

There are four species of Atherine described by naturalists. The A. hepsetus, or European Atherine, is by far the most common, being found in the North Sea, the Atlantic, and the Mediterranean. In general appearance, it much resembles the smelt. Its flesh is considered as uncommonly delicious. About the Greek Islands, according to Sonini, where it is seen in vast shoals, it is easily taken by trailing in the water a horse's tail, or a piece of black cloth fastened to the end of a pole; the fishes following all its motions, and suffering themselves to be drawn into some deep cavity formed by the rocks, are readily secured by means of a net.

Genus CC. Hydrargira.

Gill flap and ventral fins with fewer than eight rays; no teeth in the palate; one dorsal fin; lateral silvery band.

Bosc discovered in Carolina the only known species of the genus, named H. *swampina*, because it is found in the swamps or lagunes. The head is depressed, the lips are extensile, the under jaw longest. This species inhabits the fresh water marshes, and as these are sometimes nearly dried up, it is compelled to shift its haunts to deeper water, which it accomplishes by a series of leaps. The flesh is unsavoury, and little sought after, but it furnishes a grateful repast to the aquatic birds which frequent its haunts.

Genus CCI. Stolephorus.

Fewer than nine rays in the ventral fins and gill flap; one dorsal fin; no teeth; lateral silvery band.

La Cepede describes two species, viz. S. Japonicus and S. Commersonii. The former of these was first described by Houttuyn. It has five rays in the dorsal fin, while the latter species has fifteen.

Genus CCII. Mugil. *Mullet.*

Mullet.

Lower jaw carinate within; scales striated; two fins on the back.

There are seven species belonging to this genus. The most common is the M. cephalus, or common mullet, a fish well known to the ancients. It is to be found in almost all seas. This ascends rivers, like the salmon, to spawn; and at that time they congregate in vast shoals. At this time the fishermen endeavour to surround them with the net. They are said to grow very fat in rivers and lakes with a sandy bottom. They are esteemed excellent food when fresh, and are likewise often used salted. The spawn salted and dried forms a kind of caviar named botargo, which is used in Italy and the midland districts of France. The M. albula, a native of the American seas, is likewise esteemed an excellent dish for the table. In the M. crenilabis, a native of the Red Sea, both lips are curiously crenulated on the edges. The M. tang, whose flesh is fat and savoury, inhabits the rivers of Guinea. The history of the remaining species requires farther elucidation.

Genus CCIII. Mugiloides.

Lower jaw carinate within; scales striated; one dorsal fin.

The only known species, M. Chilensis, was found by Molini at Chili. It inhabits the fresh water rivers, and grows to about a foot in length.

Genus CCIV. Chanos.

Lower jaw carinate within; no teeth; scales striated; one dorsal fin; a membranaceous wing on each side the tail.

The C. Arabicus was first described by Forskael, and is the only species known. It is a native of the sea of Arabia, and was formerly inserted in the genus Mugil. The scales are large and rounded, and of a brilliant silvery colour; the head is more narrow than the body, destitute of scales, and of a green colour mixed with blue; the upper lip is grooved, and longer than the lower; the latter line is curved at its commencement, and then proceeds in a straight line to the tail. Its ordinary length is about four feet, but one variety, named *Anged*, grows to nearly twelve feet.

Genus CCV. Mugilomorus.

Lower jaw carinated within; no teeth, but protuberances in their stead; more than thirty rays in the gill flap; one dorsal fin, with an appendage to the rays.

The only known species of this genus is the Mugil appendiculatus of Bosc, the description of which was communicated by that naturalist to La Cepede. The trivial name imposed by the discoverer, was changed by the last author into Anna-carolina, in honour of his own wife.

Genus CCVI. Exocætus. *Flying Fish.*

Flying fish.

Head entirely covered with small scales; pectoral fins very large, reaching to the caudal fin; gill-flap of ten rays; one dorsal fin situated above the anal fin.

The species of this genus, which are four in number, have the power of leaping out of the water, and flying for a short distance, by the aid of their long pectoral fins. The first species is the *E. volitans*, or common flying fish, and has been long known to naturalists. It is very extensively distributed, being found in the European, American, and Indian seas. In the dorsal and anal fins there are fourteen rays; fifteen or sixteen in each of the pectoral fins; ventrals small, and placed nearer the head than the middle of the whole length of the fish. The stomach can scarcely be distinguished from the intestinal canal, and the air bag is uncommonly large. According to the observations of Plumier, as quoted by Bloch, the spawn of this species (found near the Antilles) corrodes the skin of the palate or tongue. The second species, *E. mesogaster*, has twelve rays on the dorsal and anal fins; thirteen in the pectoral fins; ventral fins placed near the middle of the animal. This species was observed by Plumier in the sea near the Antilles. The E. exiliens; the dorsal fin has eleven or twelve rays; the anal fins twelve; eighteen in each of the pectoral fins; the ventral fins long, reaching to the extremity of the dorsal fin, and situated a little beyond the middle of the body towards the tail. This species frequents the same seas as the E. volitans. It is likewise found in the Mediterranean, sometimes single, sometimes in small shoals. In shape it greatly resembles a herring; its flesh is fat and delicate. The last species, *E. comersonii*, has twelve rays in the dorsal fin, ten in the anal, and thirteen in each of the ventral fins. These last are sufficiently long to reach to the middle of the dorsal fin, and are situated beyond the middle of the body towards the anal fin. The dorsal fin is marked on the part nearest the tail with a large blue spot. It is a native of the Indian seas, where it was first found by Commerson.

Genus CCVII. Polynemus.

Free rays near each ventral fin; head covered with small scales; two dorsal fins.

La Cepede describes six species, all of which were known to former naturalists. He divides them into sections, from the form of the tail. They are chiefly the inhabitants of warmer countries. The *P. plebeius* of Broussonet is termed *P. emoi* by La Cepede; the trivial name here adopted being the appellation by which this fish is known to the natives of Otaheite. It is a native of the American, Indian, and Southern seas. The flesh is considered excellent, and hence in India this species is known by the name of *royal fish*. The inhabitants of the coast of Malabar prefer the head of the fish as a delicious morsel. In these countries it is salted and dried. M. Gazola supposes that he has found the remains of this fish in the strata of Mount Bolca. The P. paradisus, or Mango fish, is reckoned one of the best esculent fishes found at Calcutta. It is known to the natives by the name of *tupsee mutchey*. It feeds on young fishes and the crustacea.

Genus CCVIII. Polydactylus.

Free rays near each pectoral fin; head without scales; two dorsal fins.

The P. plumierii is the only known species. It bears a close resemblance to the species of the preceding genus. It is of a silvery colour; the nose is protuberant and long; the upper jaw longer than the under; the six free rays which are near the pectoral fins, resemble long threads; the second dorsal fin and the anal fin are of equal extent, placed opposite, and falcated.

Genus CCIX. Buro.

A double process between the ventral fins; one long dorsal fin; scales small and difficult to perceive; five rays in the gill flap.

The B. brunneus is the only known species, and was described by La Cepede from the MSS. of Commerson. Over the surface, there are numerous scattered small spots of a white colour; the iris is golden and silvery; head small; nose a little pointed; upper jaw moveable, and, together with the lower jaw, furnished with one row of small pointed teeth; the back and belly are carinated, and the body and tail are compressed.

Genus CCX. Clupea. *Herring.*

Herring.

Jaws furnished with teeth; more than three rays in the gill flap; one dorsal fin; belly carinated, and notched or very sharp.

La Cepede describes seventeen species of herrings, which he distributes into two sections from the shape of the tail. The most common species, C. harengus, is one of the most important to the human race in an economical and a commercial point of view. This fish is an inhabitant of the northern seas. In Europe it is seldom found farther south than the fiftieth degree of latitude, nor farther north than the sixtieth. On the coasts of America, however, it reaches farther south. The migrations of this fish have long attracted the attention of naturalists; lengthened descriptions have been given of their marvellous journies from the arctic regions, of the course which they pursue, and the obstructions which they meet with. But these descriptions have been given from a very imperfect acquaintance with the habits of the animal It is now clearly established, that the herrings, like all the other fishes that reside in deep water, approach the neighbouring shore at the season when they are ready to spawn, and return to their favourite haunts when the process of reproduction is finished The food of the herring consists of the smaller *crustacea* of young fishes, even those of their own species. At the season when they are ready to spawn, their stomachs are found empty. This fish is salted as an article of trade, the process (it is said) being first tried by William Beukelen of Biervlet near Sluys. The smoking of herrings, according to La Cepede, was first practised by the inhabitants of Dieppe. In some of the northern countries, when the herrings are in abundance, they boil them in large cauldrons, and obtain oil for their lamps; the refuse they employ as manure to the ground. The sprat, *C. sprattus*, differs from the herring in having nine rays in each ventral fin, while the herring has only six; and according to Mr Neill, "if a straight line be dropped from the fore part of the dorsal fin perpendicularly downwards, it will, in the true herring, fall a little in front of the ventral fins, but in the garvie (sprat) it will fall a little behind the same fins." This species is found in the northern countries, and also in the Mediterranean. It is used for all the purposes to which the herring is applied, and is prepared after the same manner. The *C. alosa* or *shad*, termed also from its size, mother of herrings, migrates from the sea into the fresh water rivers, like the salmon. The fry are called *white bait.* The flesh has rather a disagreeable taste. The C. encrassicolus, or anchovy, is another species of this genus held in high estimation. It inhabits the sea, and, like the herring, it approaches the shores for the purpose of spawning. The Romans expressed a pickle from this fish, which they termed a *garum.* The moderns pickle them, and as the bones dissolve entirely in boiling, the sauce is of equal value. The remaining species are chiefly the inhabitants of the seas of warmer countries. They are esculent, and possess in a greater or less degree the peculiar flavour of the herring.

Genus CCXI. Mystus.

More than three rays in the gill flap; belly carinated; anal fin very long, and united with the caudal fin. One dorsal fin.

The Clupea mystus of Osbeck is the only known species. It is a native of the Indian seas. In its general form it resembles the blade of a sword, the body and tail being greatly compressed. Upper jaw longer than the under, and furnished on each side with a flat narrow denticulated bone, which reaches to the ventral fins.

Genus CCXII. Clupanodon. *Pilchard.*

Pilchard.

More than three rays in the gill flap; belly carinated; anal and caudal fins separate; one dorsal fin; jaws without teeth.

The absence of teeth in the jaws of the Pilchard, is the mark by which, as a genus, it is distinguished from Clupea. Six species are known. The *C. pilchardus*, or common pilchard, is the most important species of the genus. It is found in great abundance on the shores of Cornwall. The flesh is considered excellent, and is eaten either fresh or salted. It contains a great deal of oil, which is extracted from it in considerable quantities by the Cornish fishermen. The C. thrissa is a native of the Indian and American seas, and ascends the fresh water rivers to spawn. The flesh is considered as fat and agreeable, but in certain circumstances it has been found to be hurtful. The C. sinensis frequents the shores and rivers of Asia and America, where it is taken in such quantities that the inhabitants manure their fields of rice with them.

Genus CCXIII. Gasteropelecus.

Head, body, and tail, compressed; belly carinated and semicircular; two dorsal fins; ventral fins very small.

This genus was instituted by Gronovius, and afterwards adopted by Bloch, for the reception of the Clupea simia of Linnæus. It has been inserted by Gmelin and some others in the genus Salmo. The two dorsal fins separate it from the herring, while the circumstance of the second dorsal fin being radiated, indicate its want of connection with the salmon. It is a native of the equatorial seas, and is said to swim very ill, on account of the peculiar shape of its body, which renders it difficult to maintain its vertical position.

Genus CCXIV. Mene.

Head, body, and tail, compressed; belly carinated and semicircular; back elevated; one low, lengthened dorsal fin; ventral fins narrow and produced.

The only species which has been taken notice of, rests on the authority of a Chinese drawing in the Dutch collection, and is termed by La Cepede, M. Anna-carolina, in honour of his wife Anne Caroline Hubert Jube La Cepede.

The generic name is indicative of its moon-shaped form.

Genus CCXV. Dorsuarius.

The anterior part of the back furnished with a compressed hunch, terminated above by a thin edge; one dorsal fin.

This genus contains at present only one species, termed *D. nigricans.* It is described by La Cepede from the manuscripts of Commerson. It was found near fort Dauphin, in Madagascar.

Genus CCXVI. Xyster.

Head, body, and tail, compressed; belly carrinated and semicircular; back elevated; gill flap of seven rays; a depression below each ventral fin.

Xyster *fuscus*, the only species which has been described, was observed by Commerson. It is of a uniform brown colour. The two jaws are rounded, and nearly of equal length; the caudal, dorsal, and anal fins, have small scales at the base; the tongue is short, large, and semicartilaginous. The nostrils have two openings each.

Genus CCXVII. Cyprinodon.

Head, body, and tail, of an ovate form; three rays in the gill flap; jaws with teeth.

The C. variegatus is from Carolina, and was first observed by Bosc. The opening of the mouth is very small; the under jaw is longest; the teeth are short; the gill lids rounded; the lateral line indistinct; iris of a golden colour. It scarcely reaches the length of four inches.

Genus CCXVIII. Cyprinus Carp.

Gill flap with four rays or more; jaws without teeth; one dorsal fin.

This very extensive genus, containing seventy species, has been subdivided into sections, from the presence or absence of the beard, and the form of the tail. These sections, we may add, are distinguished by characters more obvious and important than many of those employed by La Cepede in the construction of genera, so that we are surprised to find them still remaining in company, after witnessing so many other genera dismembered. The species are esteemed excellent food, and much sought after. The carp, which stands at the head of fresh water fishes, is well known in this country as a valuable and useful pond fish, but it is more particularly esteemed on the continent. The breeding and feeding of this fish, is there to many a source of very considerable profit. The flesh of the Barbel, *C. barbus*, is white and good, but the spawn is considered by many as hurtful. Bloch, however, is disposed to call the truth of this opinion in question, and states, that he has eaten the eggs, with all his family, without suffering any inconvenience. The scales of the C. alburnus, or bleak, are employed similar to those of the atherine, in the formation of artificial pearls. For this purpose the scales are carefully removed, and frequently rubbed against one another in water. The silvery-looking substance is then introduced, along with a solution of isinglass, into glass balls prepared for the purpose. Almost all the species may be kept in ponds, where they increase rapidly in size. They soon become acquainted with the person who feeds them, and will readily eat meat from his hand. They likewise, by habit, obey the call of a bell. When in this naturalized or domesticated state, their fins sometimes change in form and even structure, as may frequently be observed in the gold and silver fishes of China.

Division VI.

Osseous fishes with a gill-lid, but destitute of a gill-flap.

Order XXI. APODAL.

Genus CCXIX. Sternoptyx.

Body and tail compressed; under part of the body carinated and transparent; one dorsal fin.

The *S. diaphana*, an inhabitant of the West Indies, is the only known species. La Cepede has changed the trivial name into Hermann, in honour of Professor Hermann of Paris, who first described the species. The skin is apparently destitute of scales, and there is no lateral line. There are nine rays in the dorsal fin, of which one is spinous. It is a native of the island of Jamaica.

Division VII.

Osseous fishes with a gill-flap, but destitute of a gill-lid.

Order XXV. APODAL.

Genus CCXX. Stylephorus.

Eyes peduculated; snout produced, looking upwards; between which and the head there is a flexible leathery duplicature; mouth terminal; gills three on each side; pectoral fins small; dorsal fin extending from the head to the tail; caudal fin short, radiated with spines; body long, compressed.

This genus was instituted by Dr. Shaw for the reception of the S. chordatus from the West Indies. See *Lin. Trans.* vol. i. p. 90. Tab. 6. La Cepede has changed the trivial name imposed upon it by Shaw, and has substituted *argenteus* in its place.

Order XXVIII. ABDOMINAL.

Genus CCXX. Mormyrus.

Snout produced; mouth terminal; jaws with teeth; one dorsal fin.

La Cepede has described nine species of Mormyri, principally from the notes and observations of Geoffroy. They are chiefly inhabitants of the Nile.

Division VIII.

Osseous fishes destitute of a gill-lid and gill-flap.

Order XX. APODAL.

Genus CCXXI. Murænophis.

No pectoral fins; one gill opening on each side; body and tail nearly cylindrical; dorsal, caudal, and anal fins united.

This genus, the *gymothorax* of Bloch, contains twelve species. They were included by Linnæus in the genus Muræna. The first species described La Cepede is the M. helena. This is the *Muræna* of the ancients. It is found in the seas of the temperate and warmer regions of the earth. It lives with equal comfort in fresh water. The Romans constructed ponds for feeding fishes of this kind, and esteemed them as an excellent dish for the table. The memory of one Vedius Pollio is transmitted to posterity by Pliny as execrable, since he was in the practice of feeding his Murænæ with his condemned slaves. In ponds they become very familiar, and will eat food from the hand. They are cunning, and when they have swallowed the hook, make the utmost exertions to bite the line.

Genus CCXXII. Gymnomuræna.

No pectoral fins; one gill opening on each side; body and tail nearly cylindrical; no distinct dorsal or anal fin.

There are two species described by La Cepede; the G. *doliata* and *marmorata*, from the notes of Commerson. In the former, the anus is situated nearer the head than the middle of the fish; in the latter, it is nearer the tail than the head.

Genus CCXXIII. Muræno-blenna.

No distinct fins; body and tail nearly cylindrical; surface viscous.

The M. Olivacea, the only species, was found by Commerson in the Straits of Magellan. Its body is more completely enveloped in mucus than any other fish. An individual of this species, kept in alcohol for two months, was found nearly reduced to a mucilaginous oily pulp.

Genus CCXXIV. Sphagebranchus.

Destitute of fins; gill-openings two, under the neck; body and tail nearly cylindrical.

The S. *rostratus* of Bloch, and the only species of the genus, is a native of the East Indies. It has four gills on each side; the mouth is furnished with teeth; the skin has no visible scales; the snout terminates in a point; the upper jaw is longest.

Genus CCXXV. Unibranchapertura.

No pectoral fins; body and tail serpentine; one gill-opening under the neck; dorsal, anal, and caudal fins united.

This genus, the last in the system of La Cepede, contains five species. It was termed Symbranche by Bloch. The U. marmorata is a native of the fresh waters of Surinam. Its flesh is fat, but unpleasant to the taste.

Such is an outline of the system of ichthyology as given by La Cepede. In our descriptions of the genera, we have stated the more essential characters only, as we wished to prevent the article from swelling to an inconvenient length. The reader will readily perceive that the number of genera has been greatly increased

Classification of Fishes.

since the days of Linnæus. The Swedish naturalist included all the species known to him in sixty-one genera; we have enumerated two-hundred and twenty-five. We are persuaded, however, that the characters employed in the formation of not a few of the modern genera, ought to have been confined to the definition of species merely. Many of the names employed to designate the genera and species by former authors, have been suppressed by La Cepede, and new terms employed in their place, in many cases without any apology for the change being offered. We would earnestly recommend to those who cultivate this branch of Zoology, to respect and follow the excellent and judicious rules laid down by Artedi; otherwise ichthyology will continue a mere heap of rubbish, destitute of fixed principles, and a determinate nomenclature.

The reader, in perusing our account of the genera, must have been struck with the occurrence of the same genera in the same relation to other genera, in the systems of Linnæus and La Cepede, although the principles employed in the construction of the primary divisions of these two systems differ widely from each other.

BRITISH FISHES.

British fishes.

As many of our readers are probably anxious to become acquainted with the number of fishes which are natives of the seas, lakes, and rivers of the British isles, we subjoin a synoptical view of the present state of our native ichthyology. The addition of the characters by which the species are distinguished, would have augmented the list to an inconvenient length, so that we have confined our short observations, annexed to each species, to a notice of the more common provincial names and places of residence. The reader who wishes more extensive information on the subject may consult those works already enumerated in the historical part of this article, which treat of British fishes.

CARTILAGINOUS FISHES.

GENUS I. PETROMYZON. *Lamprey.*

Lamprey.

1. *P. marinus.* Sea Lamprey.

The Lamprey is common in the greater rivers of the three kingdoms, into which it enters for the purpose of spawning. In Scotland it is called *lamper eel.*

2. *P. fluviatilis.* Lesser lamprey.

Equally common with the preceding species in the same situations. It is however found in the lesser streams and rivulets into which the sea lamprey does not enter. It is the *nine eyed eel* of the Scotch.

3. *P. branchialis.* Pride or lampern.

This species is not so common as the two which we have noticed. It is found, however, in several of the English rivers.

GENUS II. GASTROBRANCHUS. *Hag.*

Hag.

4. *G. glutinosus.* Glutinous hag.

The hag is perhaps no where common on our coasts, although it has been met with at various places.

GENUS III. RAIA. *Ray or Skate.*

Ray.

5. *R. batis.* Skate or Flaire.

Common on all parts of the coast. Mr Neill informs us, that in the Firth of Forth it is called *blue skate, grey skate,* or *Dinnen skate.*

6. *R. oxyrinchus.* Sharp-nosed ray.

This is equally common as the skate, and sometimes confounded with it. In the Forth it is called *white skate, friar skate, May skate,* or *mavis skate.*

7. *R. clavata.* Thornback.

Very common on all parts of the coast. Montagu considered the R. fullonica of some authors as the male thornback. The teeth in the males of this species are sharp, and in the females blunt.

8. *R. Aspera.* Rough ray of Pennant.

This species was found by Pennant in Loch Broom. Montagu is inclined to consider it as a variety of the thornback, while Donovan regards it as the same with his R. rubus. The description left us by Pennant, would lead us to consider it as different from any of these species.

9. *R. tuberculata.* Shagreen ray.

This species was first observed by Pennant at Scarborough. It has since occurred to Montagu on the Devon coast, where it is called *dun-cow.*

10. *R. rubus.* Land ray, or French ray.

Montagu, to whom we are indebted for much valuable information with regard to the species of rays, considers the R. rubus and miraletus of Donovan as synomous, and females, while he regards the Fuller's ray of Pennant as the male. The opinion of such an eminent zoologist will always be received with respect, but we do not see the propriety of the new trivial name maculata, by which he has proposed to designate the species.

11. *R. marginata.* Bordered ray.

This species is described by La Cepede from the manuscripts of M. Noel, as having been seen by him at Liverpool and Brighton. See *Hist. Nat. des Poissons,* vol. v. p. 663. tab. 20. f. 2.

12. *R. pastinaca.* Stinging ray.

This appears to be common in the English seas, but it is very rare in Scotland. It is however mentioned by Sibbald.

13. *R. Cuvieri.* Cuvierian ray.

Mr Neil is the only British naturalist who has seen a specimen found on our coasts. It was taken in a traul net in the Frith of Forth, in summer 1808.

14. *R. radiata.* Starry ray.

This species is figured by Donovan in his British Fishes, tab. cxiv. where he says "it was caught on the north coast of Britain, and obligingly communicated to us by Mr Statchbury of the Old Jewry, London."

15. *R. microcellata.* Small-eyed ray.

This species is found on the west coast of England, and is confounded by the fishermen with the shagreen ray, and called duncow. It is described by Montagu in the *Memoirs of the Wernerian Natural History Society,* vol. ii. p. 430.

GENUS IV. TORPEDO. *Cramp Fish.*

Cramp fish.

16. *T. vulgaris.* Common cramp fish.

This celebrated fish has been taken at various places on the southern coasts of England and Ireland.

GENUS V. SQUALUS. *Shark.*

Shark.

A. With temporal orifices.

1. With an anal fin.

17. *S. catulus.* Rough hound.

The rough hound is found sparingly on all parts of the coast. It is now generally admitted by ichthyologists that the *S. canicula,* or spotted dog-fish, is merely the female.

18. *S. galeus.* Tope.

Occasionally found in the English seas, rarely off the coast of Scotland.

19. *S. mustelus.* Smooth hound.

Found on all parts of the coast. It is the *murlock* of the Frith of Forth.

British Fishes.

20. *S. vulpes.* Fox shark.

Sometimes taken in the English seas.

2. Destitute of an anal fin.

21. *S. acanthius.* Piked dog-fish.

This species swarms on the east coast of Scotland, whence it is called dog-fish. It follows the shoals of herrings, and appears to be gregarious.

22. *S. Lelanonius.* Lochfine shark.

This species is figured and described by Dr Leach in the second volume of the *Mem. Wernerian Soc.* p. 64. tab. 2. fig. 2. from a specimen obtained by the late Dr Walker from Lochfine. He considers it as the same with the basking shark of Pennant found at Loch Ransa. Stewart however inserts it in the section furnished with a temporal orifice.

B. Destitute of temporal orifices.

23. *S. carcharias.* White shark.

This formidable monster is occasionally found in our seas. The jaws of one taken in the Pentland Frith are now before us.

24. *S. maximus.* Basking shark.

This is common in the Scottish seas. On the west coast it is called *sail-fish, sun-fish, or cairban*; in Orkney it is called *Homer,* and in Zetland *brigdie.*

25. *S. glaucus.* Blue shark.

The blue shark frequents the coasts of Cornwall chiefly during the pilchard season.

26. *S. cornubicus.* Porbeagle shark.

Occasionally found in the sea at different parts of the coast. It is the same as the Beaumaris shark.

Genus VII. Squatina. *Angel Fish.*

Angel fish.

27. *S. vulgaris.* Common angel fish.

Found on many parts of the coast. In some places in England it is called fiddle-fish or puppy-fish. It has been repeatedly taken in the frith of Forth.

Halsydrus. *Sea Snake.*

Sea snake.

28. *H. pontoppidiani.* Sea snake.

This is the great sea snake of the Orkney islands, already taken notice of.

Genus IX. Lophius. *Angler.*

Angler.

29. *L. piscatorius.* Common angler, or fishing frog.

Common on all parts of the coast. In Scotland it is called *wide-gab, or mulrein.*

30. *L. cornubicus.* Mounts-bay angler.

This species is described by Borlase in his History of Cornwall, 266. Tab. 27. fig. 6. Donovan seems disposed to conclude, but apparently without sufficient reason, that the description of this fish must have been taken from a dried specimen of the common angler.

31. *L. Fergusonii.*

This species is described in *Phil. Trans.* vol. liii. p. 170. and figured tab. 13. It was taken in King Road near Bristol. It is quoted by Pennant as synonymous with the L. cornubicus, although its characters are sufficiently obvious to point out a specific difference.

Genus XI. Chimæra. *Sea Monster.*

Sea monster.

32. *C. monstrosa.* Arctic sea monster.

Occasionally found in the Scottish seas, rarely on the English shores.

Genus XIII. Acipenser. *Sturgeon.*

Sturgeon.

33. *A. sturio.* Common sturgeon.

Frequently found in the salmon nets in the large rivers.

Genus XV. Tetrodon. *Sun Fish.*

Sun fish.

34. *T. mola.* Common sun fish.

This fish has been frequently taken in the frith of Forth. It was common on the Cornish coast in the days of Borlase.

35. *T. truncatus.* Oblong sun fish.

This species is occasionally found in the English seas, where they have been taken of five hundred pounds in weight.

36. *T. stellatus.* Starry sun fish.

This is the globe Diodon of Pennant. It is of rare occurrence on the English shores, although common in the seas of more southern latitudes.

Genus XIX. Syngnathus. *Pipe Fish.*

Pipe fish.

37. *S. typhle.* Short pipe fish.

Found on all the British shores, lurking among the sea weeds in shallow water.

38. *S. acus.* Needle pipe fish.

This is so nearly allied to the preceding in character and habit, that doubts are entertained by many naturalists as to the propriety of continuing it as a distinct species.

39. *S. pelagicus.* Pelagic pipe fish.

This is caught in the winter season among the sprats on the English coast, and was first described as British by Donovan.

40. *S. equoreus.* Equoreal pipe fish.

We owe the knowledge of the occurrence of this species on the English shores to the late Mr Montagu.

41. *S. barbarus.* Long pipe fish.

This has been found on different parts of the coasts of England and Scotland.

42. *S. ophidion.* Snake pipe fish.

This is a species of frequent occurrence. It is, unlike its congeners, said to be oviparous.

Genus XX. Cyclopterus. *Sucker.*

Sucker.

43. *C. lumpus.* Lump sucker.

This is frequent on all the coasts, and is sometimes brought to market.

44. *C. liparis.* Unctuous sucker.

This species is taken on our coasts, but it is a fish rather of rare occurrence.

45. *C. bimaculatus.* Bimaculated sucker.

First described and figured by Pennant, from the communications of the Duchess Dowager of Portland. It has been found at several places on the English coast.

46. *C. Montagui.* Montagu sucker.

This species was first observed by the late Mr Montagu, and named in honour of him by Mr Donovan. It was found by him on the coast of Devon.

Genus XXI. Lepadogaster.

47. *L. gouani.* Lesser sucking fish.

Sucking fish.

This is the Jura sucker of Pennant. It has been found in the sea at the island of Jura, and on the coasts of Cornwall and Devon.

Genus XXIV. Centriscus. *Trumpet Fish.*

Trumpet fish.

48. *C. scolopax.* Snipe trumpet fish.

This fish has been taken on the coasts of Devon and Cornwall according to Donovan, who first introduced it into the list of the British species.

OSSEOUS FISHES.

Genus XXVII. Leptocephalus.

49. *L. morrisii.*

This species was first observed by Mr William Morris in the sea near Holyhead, and has since been found by several English naturalists.

XXIX. Genus Trichiurus. *Blade Fish.*

50. *T. lepturus.*

Blade fish.

A specimen of this fish was cast ashore in the Moray Frith, near Gordon Castle, which was about 12½ feet in length without the head. An account of it by Mr Hoy is published in the Linnæan Transactions, vol. xi. part 2d.

Sea serpent.

GENUS XXXI. OPHISURUS. *Sea Serpent.*

51. *O. ophis.* Spotted sea serpent.

This species was first described as British by Merret in his *Pinax*, page 185, under the title Serpens Marinus. It was omitted by Pennant in his British Zoology, but continued by Berkenhout and others.

Eel.

GENUS XXXVI. MURÆNA. *Eel.*

52. *M. anguilla.* Common eel.

Found in lakes, ditches, and rivers throughout the kingdom. In many places, they appear to live in the sea during the winter, from whence in spring they migrate to the fresh waters. They return again in harvest, and at that season are considered as in the best state for the table.

53. *M. conger.* Conger eel.

Common in the sea.

54. *M. myrus.* This species inhabits the Mediterranean, and is inserted in the list of British fishes on the authority of Berkenhout.

GENUS XXXVII. AMMODYTES. *Launce.*

Launce.

55. *A. Tobianus.* Sand launce, or sand eel.

Found in the sea on the sandy shores. Is less common in the northern than in the southern parts of the island.

GENUS XXXVIII. OPHIDIUM.

56. *O. barbatum.*

This species is well known as a native of the Mediterranean and Red Seas. It is inserted in the British list on the authority of Berkenhout.

57. *O. imberbe.*

First described as British by Pennant, who obtained it from the sea near Weymouth. Montagu found it on the south coast of Devon, and has published a minute description of it in the *Memoirs of the Wernerian Nat. Hist. Soc.* vol. i. p. 95. t. iv. f. 2.

XL. ZIPHIAS. *Sword Fish.*

Sword fish.

58. *Z. gladius.* Common sword fish.

Willoughby states, that he has seen a fish of this species in England fifteen feet in length. It is, however, a fish of rare occurrence.

59. *Z. rondelatii.*

This species is described by Dr Leach in the *Memoirs of the Wernerian Society*, vol. ii. p. 58. He considers it the Ziphias or Gladius of Rondeletius, although it has a second anal fin, of which that author takes no notice. We are inclined to consider these as belonging to one species, and to attribute the differences in the accounts which have been given of them to the imperfection of the specimens described.

GENUS XLII. ANARCHICHAS. *Wolf-Fish.*

Wolf fish.

60. *A. lupus.* Common wolf-fish.

Frequent on the coast, especially in the northern parts of the island, where it is called *Cat-fish.*

GENUS XLVII. CALLIONYMUS. *Dragonet.*

Dragonet.

61. *C. lyra.* Gemmeous dragonet.

Common in the Frith of Forth, where it is called *Gowdy.* The female, or sordid dragonet of naturalists, is called *Sting-fish* on the coast of Devon.

GENUS IV. TRACHINUS. *Weever.*

Weever.

62. *T. major.* Greater weever.

Pennant is the first naturalist who describes this species. It inhabits the sea near Scarborough, and is occasionally brought in the spring to the London market.

63. *T. draco.* Common weever.

Not uncommon on the English coasts. Rare in the Scottish seas.

GENUS XLI. GADUS. *Cod.*

Cod.

SECTION II. *With three dorsal fins, chin bearded.*

64. *G. morhua.* Common cod.

This is found in the sea in all parts of the island, but the greatest fisheries are on the Scottish coasts. Their capture gives employment to a great number of seamen.

65. *G. æglifinus.* Haddock.

Equally common as the cod, but more capricious in its migrations. Haddocks have appeared in the Frith of Forth in the month of June this year, in great numbers, after a partial absence of several years.

66. *G. callarias.* Dorse.

Inserted on the authority of Willoughby. It is not mentioned by Pennant or Donovan.

67. *G. luscus.* Bib.

This species is nowhere found in any numbers, and is seldom sought after.

68. *G. barbatus.* The pout.

It is not a common species. By the Scarborough fishermen it is called Fleg, and its flesh is considered delicate.

69. *G. minutus.* Poor.

This species, common in the Mediterranean, was observed on the Cornish coast by the Rev. Mr. Jago.

70. *G. punctatus.* Speckled cod.

This species, which is said to be frequently taken in the weirs at Swansea, is described by Dr. Turton in his *British Fauna*, p. 90.

SECTION II. *With three dorsal fins; chin beardless.*

71. *G. carbonarius.* Coal fish.

Very common, especially in the tideways in the northern islands. When young they are good to eat, but when full grown they are very coarse and unpalatable.

72. *G. merlangus.* Whiting.

Taken in the spring months in considerable numbers, on all the coasts of the island.

73. *G. pollachias.* Pollack.

Common on the English coast, and on the west coast of Scotland, but seldom found on the east. At Scarborough they are called *Leets*, with us *Lythes.*

74. *G. virens.* Green cod.

This species is not uncommon in the northern seas. It was first described as British by Pennant, from the observations of Sir John Callum.

SECTION III. *With two dorsal fins; chin bearded.*

75. *G. molva.* Ling.

Common on all parts of the coast. In the northern islands, the salting of these fish for exportation is a considerable article of trade.

76. *G. lota.* Burbot.

This species lives in the fresh water, and prefers clear waters, where the current is slow. It is unknown in Scotland, and in England it is found only in a few rivers. Its flesh is excellent, and eagerly sought after.

77. *G. mustela.* Five bearded cod.

Not uncommon on the English shores. First accurately discriminated by Pennant.

78. *G. argenteolus.*

This is a new species, described by Montagu in the 2d volume of the *Memoirs of the Wernerian Nat. Hist. Society*, p. 449. It is common on the western coast of England, and is more nearly allied to the three bearded cod than to any other of the genus.

79. *G. triarratus.* Three bearded cod.

This is a common species, frequenting the rocky parts of the coast. By some it has been injudiciously considered as a variety of the five bearded cod.

SECTION IV. *With two dorsal fins; chin beardless.*

80. *G. merluccius.* Hake.

This fish is unknown in Scotland, and is seldom seen on the east coast of England; but in the south-west shores of that kingdom, and on the south-east shores of Ireland, it is found in great shoals, and caught for the market. It is not held in high estimation, as its flesh is soft and insipid.

SECTION V. *With one dorsal fin; chin bearded.*

81. *G. brosme.* Tusk.

This species is chiefly found in the seas around the Zetland islands. It is rare in Orkney, and very seldom found to the south of the Pentland Frith. Considerable confusion has arisen in the determination of the synonymes of this fish, in consequence of calling our fish *torsk* instead of *tusk*, as the former name on the continent designates a very different species.

We are aware that several other species of cod have been described by naturalists as natives of our seas, but their claims to rank as distinct species have not been satisfactorily ascertained.

GENUS LIII. BLENNIUS. *Blenny.*

Blenny.

SECTION I. *Two dorsal fins; head with tentacula.*

82. *B physcis.* Forked Blenny.

First observed by Mr Jago on the Cornish coast. It is the Forked Hake of the British Zoology.

SECTION II. *One dorsal fin; head with tentacula.*

83. *B. ocellaris.* Ocellated Blenny.

This well known Mediterranean species, was found in the year 1814 by the late Mr Montagu, at Torcross, Devonshire, and is figured and described by him in the second volume of the *Memoirs of the Wernerian Nat. Hist. Society.* La Cepede has erroneously placed this in his first section, as if it had two dorsal fins, and has, without sufficient reason, changed the trivial name into lepus.

84. *B. gattoruginea.* Gattorugine Blenny.

Described by Pennant as having been found on the coast of Anglesea. Montagu has likewise met with it on the south coast of Devon.

85. *B. galerita.* Crested Blenny.

It is found on the rocky shores of the English coast, but is by no means a common species.

86 *B. Montagui.*

This species is described at length, and figured by Montagu in the first volume of the *Memoirs of the Wernerian Nat. Hist. Society.* He entertains doubts as to its claims to rank as a species distinct from the preceding, although its characters are sufficiently well marked.

SECTION III. *One dorsal fin; no tentacula on the head.*

87. *B. pholis.* Smooth Blenny.

This species is found plentifully on the south coast of England under stones.

88. *B. viviparus.* Viviparous Blenny.

This is the most common species, being found near the shore under stones, and among the sea-weed at all parts of the coast.

89. *B. gunnellus.* Spotted Blenny.

This is equally common with the last in the same situations. Mr Low, in his *Natural History of Orkney,* notices a fish allied to this species, which he calls Purple Blenny. He says, "I should almost take it for a variety, (of B. gunnellus) were it not the colour is different; being in this reddish purple; the fins lightest, and of the same shape and size of the former. It likewise wants the spots on the back, the other has; instead of eleven in the former, this has only a single one, and that placed near the beginning of the back fin. In other circumstances, both of its shape and way of life, it agrees altogether with the former." Fabricius and other naturalists have described several varieties of the gunnel blenny, differing chiefly in the number and colour of the spots.

GENUS LVII. LEPIDOPUS. *Scale-foot.*

Scale foot.

90. *L. tetradens.* Four-toothed Scale-foot.

The late Mr Montagu described and figured this species for the first time as a British fish, in the *Memoirs of the Wernerian Nat. Hist. Society,* vol. i. p. 81. Tab. 2. It was taken in Salcomb harbour on the coast of South Devon in 1808. A smaller specimen occurred near the same place two years afterwards.

GENUS LIX CEPOLA. *Band-fish.*

Band fish.

91. *C. rubescens.* Red Band-fish.

The only British specimen of this fish which has occurred, was caught in Salcomb bay on the 25th of February 1803; and figured and described by Montagu in the seventh volume of the *Linnæan Transactions,* p. 219. Tab. 17.

GENUS LXI. GOBIUS. *Goby.*

Goby.

92. *G. niger.* Black Goby.

Not uncommon on the English coast, where it is termed *Rock-fish.* Sometimes found on the west coast of Scotland.

93. *G. minutus.* Spotted Goby.

This species, which is frequent on the English shores, is likewise found on those of Scotland. It is chiefly obtained from the shrimp nets.

GENUS LXVI. SCOMBER. *Mackrel.*

Mackrel.

94. *S. scomber.* Common Mackrel.

Common on all parts of the coast, principally during the autumn months. The Coly Mackrel of some authors appears to be only a variety.

95. *S. thynnus.* Tunny Mackrel.

Not uncommon on the west coast of Scotland. They appear to be rare on the English coast.

96. *S. pelamis.* Bonito.

We insert this in the British list on the authority of Stewart, who, in his *Elements of Natural History,* 2d edit. vol. i. p. 363, says, "It has been taken, though rarely, in the Frith of Forth."

GENUS LXVIII. CARANX. *Scad.*

Scad.

97. *C. trachurus.* Common Scad.

This is a rare fish on our coasts. It has occurred to Pennant and Donovan, but few other British naturalists have met with it.

GENUS LXXXIV. ECHINEIS. *Sucking Fish.*

98. *E. remora.* European sucking fish.

This fish holds its place in the British list on the authority of Turton, who says, in his *British Fauna,* p. 94, "taken by the author, in Swansea, from the back of a cod fish, in the summer of 1806.

GENUS LXXXIX. ASPIDOPHORUS. *Pogge.*

Pogge.

99. *A. cataphractus.* Mailed pogge.

Common on all parts of the coast. It ascends the large rivers as far as the water is brackish.

GENUS XCI. COTTUS. *Bull Head.*

Bull head.

100 *C. gobio.* River bull head.

Frequent in England in the clear brooks.

101. *C. scorpio.* Father lasher.

This is a very common species. It is found in all parts of the coast, and sometimes ascends the larger rivers, into brackish water.

Stickle back.

GENUS XCIV. GASTEROSTEUS. *Stickle Back.*

102. *G. aculeatus.* Three spined stickle back.

Common in rivers and ditches. During floods it is sometimes swept into the sea, where it attains a greater size than in fresh water.

103. *G. pungitius.* Ten spined stickle back.

Chiefly found on the coast. Is rare in Scotland.

104. *G. spinachia.* Fifteen spined stickle back.

Inhabits the sea. It appears to be a weak fish, as it is frequently cast ashore by the tide.

GENUS CII. TRIGLA. *Gurnard.*

Gurnard.

105. *T. gurnardus.* Grey gurnard.

This is very common on all parts of the coast. Being easily taken, it is much used as food by the crews of our coasting vessels.

106. *T. cuculus.* Red gurnard.

Common on the English coast. Unknown in Scotland.

107. *T. Lyra.* Piper.

Found on the western coasts of England, where it is held in some estimation.

108. *T. hirundo.* Sapphirine gurnard.

This remarkably beautiful fish is found on the coast of Wales and Devonshire.

109. *T. lastoviza.* Streaked gurnard.

The species described by Donovan as the streaked gurnard, *Trigla lineata*, tab. iv. appears referable to this species of La Cepede, from the coincidence of the numbers of the rays of the fins. The last author, however, is silent with respect to the branching of the thread-like ridges on the belly. The specimen which Donovan figures, was taken on the eastern coast of England.

110. *T. lineata.* Lineated gurnard.

This is the species originally described by Mr Jago, and introduced into the *British Zoology* by Mr Pennant. It has been taken on the coast of Devon in great abundance, by the late Mr Montagu. In this species the ridges are not branched, and do not reach the length of the belly.

111. *T. lævis.* Smooth gurnard.

This is a new species, found on the coast of Devon, described by Montagu in the second volume of the *Memoirs of the Wernerian Natural History Society*, p. 455. "It is taken," he says, "by the shore nets as well as by hook, the finest when fishing for whiting, by a bait of Launce. It is sometimes called Yellock, at Torcross, by the fishermen, but generally confounded with the Sapphirine, the Red and the Streaked (lineated) gurnards, under the denomination of Tub."

GENUS CV. GYMNETRUS.

112. *G. Hawkenii.*

Dr Shaw, in his *General Zoology*, vol. iv. p. 198, after describing this species, says, "it appears from a print published in the year 1798, that a specimen of this fish was thrown on the coast of Cornwall in the month of February in the same year. Its length was eight feet six inches, its breadth in the widest part ten inches and a half, and its thickness only two inches and three quarters. The tail in this specimen was wanting. The colours the same as in the specimen figured by Dr Bloch."

GENUS CVI. MULLUS. *Surmullet.*

Surmullet.

113. *M. barbatus.* Red surmullet.

The only evidence of this species being found in our seas, is the following passage in the *British Zoology*: "We have heard of this species being taken on the coast of Scotland, but had no opportunity of examining it; and whether it is found on the west of England with the other species or variety, we are not at this time informed."

114. *M. surmuletus.* Striped surmullet.

This species is not uncommon on the English coast, and has been considered by some as merely a variety of the former species, an opinion with which we are disposed to agree.

GENUS CX. LABRUS. *Wrasse.*

Wrasse.

115. *L. gibbus.* Gibbous wrasse.

Inhabits the coast of Anglesea, and first described by Pennant as a British species.

116. *L. trimaculatus.* Trimaculated wrasse.

First observed by Pennant on the coast of Anglesea, and afterwards on the coast of Devon. In the Frith of Forth it is called the *Sea Perch.*

117. *L. cornubicus.* Goldfinny.

This appears to be a common species, and was first observed by Mr Jago in Cornwall. In the Frith of Forth, according to Mr Neill, it is called the *Brassy.*

118. *L. julis.* Indented striped wrasse.

This species was observed by Miss Pocock on the coast of Cornwall in the year 1802, and is figured by Donovan in his *British Fishes*, tab. 96.

119. *L. tinca.* Ancient wrasse.

Not uncommon on the English shores. It has likewise been found in the Frith of Clyde.

120. *L. bimaculatus.* Bimaculated wrasse.

Brunich observed this species at Penzance, on whose authority it was inserted in the *British Zoology.*

121. *L. variegatus.* Striped wrasse.

Pennant obtained this species off the Skerry isles, on the coast of Anglesea, from which place Donovan likewise obtained specimens.

122. *L. coquus.* Cook wrasse.

This is rather a doubtful species, as no naturalist has found it since the time of Mr Jago.

123. *L. lineatus.* Streaked wrasse.

This species is figured by Donovan in his *British Fishes*, tab. 74, as a new species. It was taken on the Cornish coast, where it is called *green fish.*

124. *L. comber.* Comber wrasse.

This species is but little known. Pennant says, "I received this fish from Cornwall, and suppose it to be the comber of Mr Jago."

GENUS CXVII. SPARUS. *Gilt Head.*

Gilt head.

125. *S. aurata.* Lunulated gilt head.

This species is not uncommon on the coast of Wales; in other parts of this country it may be considered as rare.

126. *S. pagrus.* Red gilt head.

Not uncommon on the coast of Devon, where it is taken near the shore by the hook, and in nets.

127. *S. lineatus.* Black gilt head.

This species, which Montagu considered a non-descript, and which he has figured and described in the *Memoirs of the Wernerian Natural History Society*, vol. ii. p. 451, tab. xxiii. is frequent on the coast of Devon, in company with the preceding species.

128. *S dentex.* Four toothed gilt head.

This species has been added to the list of British fishes by Mr Donovan. It is figured at tab. lxxiii. of his British Fishes, from a specimen caught in the sea off the coast of Hastings in Sussex.

129. *S. Raii.* Rayan gilt head.

This species was first observed by Mr Johnston, who communicated it to Ray. By this author it was described under the title, "Brama marina cauda forcipata." Pennant describes it as the *toothed gilt head.* Bloch afterwards gave a figure of it under the name of S. Raii. La Cepede rejects the name which Bloch had bestowed on it, substitutes a French provincial name in its place, and named it S. castaneola. Shaw, to increase the difficulty, describes two spari, S. Raii and S. castaneola, as if they were distinct species. Amidst so many changes, it is surprising that no one has done justice to Johnston, to whom we owe its discovery. This is a rare species in England, but it has frequently occurred on the east coast of Scotland.

GENUS CXX. CENTROPOMUS. *Basse.*

Basse. 130. *C. punctatus.*

This is the Perca labrax of Linnæus. It is frequent on the English coast, and is sometimes taken in the Frith of Forth. Its flesh is prized as excellent food.

GENUS CXXV. HOLOCENTRUS.

131. *H. cernua.* Ruffe.

This is found in several of the English streams, but appears to be unknown in Scotland. It is the Perca cernuca of Linnæus.

132. *H. Norvegicus.* Sea Perch.

This species has generally been confounded with the Perca lineis utrinque septem transversis of Artedi, the Perca marina of Rondeletius, Willoughby, Belonius, and Salvianus. This last, however, has ten spinous rays and fifteen branched ones in the dorsal fin, while our species has fifteen spinous and fourteen branched rays in the same fin. The H. Norvegicus is rather a rare species on our coasts. In the northern islands of Scotland it is called *Bergylt.*

GENUS CXXVI. PERCA. *Perch.*

Perch. 133. *P. fluviatilis.* Common Perch.

This is common in many parts of our island in lakes. In the north of Scotland it is a rare fish.

GENUS CXLIX. ZEUS. *Doree.*

Doree. 134. *Z. faber.* Common Doree.

Found on the English coast, and brought to market. It is rare on the coast of Scotland.

GENUS CLI. CHRYSOTOSUS. *Opah.*

Opah. 135. *C. luna.* Common Opah.

Various instances are on record of this fish having been cast ashore on the Scottish shores. It has likewise been observed on the English coast.

GENUS CLIII. PLEURONECTES. *Flounder.*

SECTION I. *Eyes on the right side.*

Flounder. 136. *P. hippoglossus.* Holibut.

Common on all parts of the coast. In the Scottish markets it goes by the name of *Turbot.*

137. *P. limanda.* Dab.

This species is equally common as the last on all our shores. In the Edinburgh market it is termed *Saltie* or *Salt Water Fleuk.*

138. *P. Solea.* Sole.

The principal fisheries are on the western coasts of England. In Scotland they are in a great measure neglected. They occasionally enter our large rivers, and seem capable of living in brakish water.

139. *P. platessa.* Plaise

Very common on all parts of the coast.

140. *P. flesus.* Common Flounder.

Common, subject to variations in colour. The *P. roseus* of Shaw's General Zoology, vol. iv. p. 302. tab. 43.* is a rose-coloured variety. The P. passer of Linnæus is a reversed variety, having the eyes on the left side.

141. *P. microcephalus.* Smear Dab.

This species is found on the southern and western coasts of England, and was first figured and described by Donovan in his British Fishes, tab. 42.

142. *P. variegatus.* Variegated Sole.

This is another species, for the discovery of which we are indebted to Donovan. He has figured and described it in his British Fishes, tab. 107. It was found along with other flat fish in the Billingsgate market.

143. *P. limandula.* Smooth Dab.

This is the Smear Dab of Pennant, and is sometimes found on the English stalls.

144. *P. arnoglossus.* Lantern fish.

This is the smooth sole of Pennant. It was described by Ray, but has not been observed by any naturalist since his time.

SECTION II. *Eyes on the left side.*

145. *P. maximus.* Turbot.

Common on all parts of the coast, and highly prized.

146. *P. rhombus.* Brill or Pearl.

Common on the English coast. Mr Neill says that it is found in Aberlady bay, and is called *Bonnet Fleuk.*

147. *P megastoma.* Whiff.

This is the Whiff of Ray, and has been confounded with the Brill and the Spotted Flounder by the continental ichthyologists. It is not uncommon on the English shores.

148. *P. punctatus.* Spotted Flounder.

This species has been observed among the Zetland isles, and likewise on the English coast. It is described in the Wernerian Mem. vol. ii. p. 241.

149. *P. cyclops.* Cyclops Flounder.

This new species of flounder was discovered by Captain Merrick of Aberfraw in Anglesea, and has been described and figured by Donovan in his British Fishes, tab. 90.

GENUS CLVII. COBITIS. *Loche.*

150. *C. barbatula.* Common loche. Loche.

This is a very common fish in our small rivers and streams. In England it is frequently called the *groundling,* in Scotland the *lying loche.*

151. *C. tænia.* Armed loche or groundling.

This species, which is not mentioned by Pennant, is found in the Trent, according to Berkenhout, and is said by Turton to inhabit the clear streams of Wiltshire.

GENUS CLXXX. SALMO. *Salmon.*

152. *S. salar.* Common salmon. Salmon.

Common in all the large rivers, and a species of vast commercial importance. The fisheries are regulated by laws which should be revised, as they are founded, in some instances, on mistaken notions with respect to the habits of the fish, and are exceedingly partial in their operation.

153. *S. eriox.* Grey.

This species was first described by Ray. They are found in several of the rivers of England and Scotland. The tail is even at the end, the spots on the body are large, round, and purplish. The flesh when boiled is pale pink coloured.

154. *S. trutta.* Salmon trout.

This species, like the preceding, migrates from the sea into the rivers to spawn, and is very common. It is often termed the *sea-trout,* or the *bull-trout.*

155. *S. fario.* River trout.

This is the most common species, and is found in all our rivers and streams. It varies in colour according to the qualities of the water in which it resides.

156. *S. salvelinus.* Red-belly.

This is an alpine species, and appears to be common to the lakes of Wales and Scotland. It was first distinctly pointed out as a British fish by Donovan in his *British Fishes*, tab. 112.

157. *S. alpinus.* Char.

Frequent in the larger lakes in the middle and southern parts of the kingdom.

158. *S. Cambricus.* Sewin.

This fish is figured and described by Donovan in his *British Fishes*, tab. 91. It is very common in Wales. It appears to have been confounded with the S. eriox, and even with the Sheiffer mulleri of Bloch, but the form of the tail and of the spots furnish sufficient characters of distinction.

159. *S. albus.* White.

This species is described by Pennant in his *British Zoology*, as inhabiting the Esk in Cumberland. He considers it as the Phinock of the Scots. Is the S. cumberland of La Cepede specifically distinct?

GENUS CLXXXI. OSMERUS. *Smelt.*

Smelt.

160. *O. eparlanus.* Smelt or Spirling.

This species frequents many of the larger rivers, and is gregarious. It feeds upon the smaller crustacea.

GENUS CLXXXII. COREGONUS.

161. *C. lavaretus.* Gwiniad.

This is common in some of the Welch lakes, and is likewise found in those of Scotland.

162. *C. thymallus.* Grayling.

Common in many of the English rivers. Mr Low, in his Natural History of Orkney, p. 224, informs us that it is very common in that country.

163. *C. albula.* Juvangis.

Stewart, in his *Elements of Natural History*, vol. i. p. 373, refers the *Juvangis* of Lochmaben to this species. Mr Pennant considered it as the Gwiniad. In the *Statistical Account of the Parish of Lochmaben*, vol. vii. p. 236, it is said that "they have a mark of a heart on the head."

164. *C. clupeoides.*

This species, described by La Cepede from the communications of M. Noel, is the *fresh water herring* of Loch Lomond. According to the observations of Dr Stewart of Luss, however, it is the gwiniad, and is also called powan and pollag.

GENUS CLXXXVIII. ESOX. *Pike.*

Pike.

165. *E. lucius.* Common Pike.

This fish, which is now found in many of the lakes and rivers of this kingdom, is said to have been introduced into England in the reign of Henry VIII. in 1537. But as *pykes* and *breams* are stated to have been served up in plenty, at the feast given by the Archbishop of York in 1466, it is probable that even at that time pikes were not uncommon in the country. In the south of Scotland it is called *ged.*

166. *E. belone.* Gar pike.

The gar pike is taken on all our coasts, and in general makes its appearance with the mackrel. We have seen specimens thrown ashore in the winter season in the northern islands.

GENUS CXCI. LEPISOSTEUS. *Gar-fish.*

Gar-fish.

167. *L. Osseus.* Common gar-fish.

This species was first described as British by Berkenhout, as having been found on the Sussex coast. Mr Stewart, in his *Elements of Natural History*, 2d edit. vol. i. p. 374, adds that it has been taken in the Frith of Forth.

GENUS CXCIII. SCOMBERESOX. *Saury.*

Saury.

168. *S. saurus.* Common saury.

Ray was the first who described this species as British under the name *skobster* or *skipper*, and as inhabiting the coasts of Cornwall. Pennant afterwards contributed to make it more generally known. It has since been found by several naturalists on various parts of the coast. In the Frith of Forth it is called *gowdnook*, or *gaufnook*, and sometimes *Egyptian herring*.

GENUS CXCVII. ARGENTINA. *Argentine.*

Argentine.

169. *A. sphyræna.* Pearly Argentine.

First described as British by Pennant. It is a rare species, and has seldom come under the observation of British ichthyologists. Mr Low in his *Nat. Hist. of Orkney*, p. 225. examined one found on the shores of that country.

GENUS CXCVIII. ATHERINA. *Atherine.*

Atherine.

170. A. *hepsetus.* European Atherine.

According to Pennant, this fish is very common in the sea, about Southampton, and Donovan obtained them from the coast of Devon. In Scotland, according to Mr Neill, they are found washed ashore in the Frith of Forth, and we have observed young specimens in the Tay.

GENUS CCI. MUGIL. *Mullet.*

Mullet.

171. *M. cephalus.* Common Mullet.

This fish is found on many of our shores, near the mouths of rivers, both in Scotland and England.

GENUS CCV. EXOCŒTUS. *Flying Fish.*

Flying fish.

172. *E. volitans.* Common Flying Fish.

There is but one instance on record of this fish having been found on our shores. In June 1765 one was caught at a small distance below Caermarthen, in the river Towy, being brought up by the tide, which flows as far as the town. An account of it was communicated to Pennant, by John Strange, Esquire, at Caermarthen, who saw the fish.

GENUS CCIX. CLUPEA. *Herring.*

Herring.

173. *C. harengus.* Common Herring.

Very common on the coasts of Scotland and the north of England. Those which are caught on the west coast of Scotland, are preferred to those taken on the east, as being larger and fatter, from their living in deeper water.

174. *C. sprattus.* Sprat.

This is frequently confounded with the herring fry. It is much more frequent in England than in Scotland. With us it is called *garvy.*

175. *C. alosa.* Shad.

This fish is not uncommon in the great rivers, into which it enters to spawn. It feeds on young herring and other small fishes. Above and below the forked division of the tail on both sides, we have observed subsidiary finlets or plaits, which do not appear to be taken notice of by authors.

176. *C. encrassicolus.* Anchovy.

This species has hitherto been met with but sparingly on our shores. Ray observed it in the estuary of the Dee. Pennant obtained it in Flintshire, and Donovan from the coast of Hampshire.

GENUS CCXI. CLUPANODON. *Pilchard.*

Pilchard.

177. *C. pilchardus.* Common Pilchard.

This fish is occasionally seen in the Scottish seas, but it appears to be very common on the Cornish shores. It is very distinct from the herring, with which, however, it has been often confounded.

GENUS CCXVII. CYPRINUS. *Carp.*

SECTION I. *Bearded.*

Carp.

178. *C. carpio.* Common Carp.

This fish is a native of the warmer countries of Europe, but on account of the excellence of its flesh it has been naturalized in many of the northern kingdoms. It is generally said to have been introduced into England about the year 1514 by Leonard Maschal. But Mr Donovan proves, from a passage in the *Boke of St Alban's*, by *Wynken de Worde*, published in the year 1496, that it was known in England at that period, although considered as rare. A few unsuccessful attempts have been made to translate them into Scotland, where it is said they will not breed in the ponds.

179. *C. barbus.* Barbel.

This is common in the still, deep parts of the English rivers. It is not known as an inhabitant of Scotland, into which, however, it might easily be translated.

C. gobio. Gudgeon.

This is a very common fish in England, being found in almost all the streams and pools of fresh water. It is unknown in Scotland.

180. *C. tenca.* Tench.

It inhabits tranquil waters, and is common in the lakes and rivers of England. The only evidence of its being found in Scotland is in the Statistical Account of the parish of Inch in Galloway, by the Rev. Peter Ferguson. Speaking of the lakes in the parish, he says "they abound in pike, perch, carp, *tench*, roach, white and red trout." *Stat. Ac. Scot.* vol. iii. p. 137.

SECT. II. *Beardless.*

181. *C. carassius.* Crusian.

According to Pennant, this species is common in many of the fish ponds about London, and other parts of the south of England. He believes that that is not a native fish. It is not however ascertained by whom, or at what period it was introduced.

182. *C. phoxinus.* Minnow.

This gregarious species is found in almost every gravelly stream.

183. *C. leuciscus.* Dace.

The dace is very common in the early part of summer in many of the English rivers. It is unknown in Scotland. The *graining* of Pennant, found in the Mersey, appears to be a variety of this species; it is the C. Lancastriensis of Shaw. *General Zoology*, vol. v. p. 234.

184. *C. rutilus.* Roach.

This is found in many of our deep rivers and lakes. It is rare in the eastern parts of Scotland; but on the west it is common, and known by the name of *Braise* or *Gilt-head.*

185. *C. idus.*

This species is inserted as British on the authority of Mr Stewart in his *Elements of Natural History*, 2d edit. vol. i. p. 382, who says, "Found in the Nith by Dr. Walker."

186. *C. orfus.* Rudd, or Finscale.

This Linnæan species is unquestionably the Rutilus latior of Willoughby, and minutely described by him as a native of the English Lakes.

187. *C. erythropthalmus.* Red Eye.

This species is figured by Donovan, tab. xl. We may observe that disputes have arisen about our English Rudd; some supposing it the *orfus* of Linnæus, while others regard it as the *erythropthalmus.* To us it appears extremely probable, that both species are found in our lakes; and had the descriptions of Pennant and Donovan been as copious and minute as that of Willoughby, all doubts upon the subject would easily have been removed.

188. *C. Jeses.* Chub.

The chub is common in the deep holes of rivers in England: in Scotland, according to Pennant, it is found in the Annan.

189. *C. alburnus.* Bleak.

Very common in some of the English rivers; unknown in Scotland.

190. *C. brama.* Bream.

The bream is common in the lakes and deep parts of rivers in England and Ireland: in Scotland it is found in Lochmaben.

191. *C. auratus.* Gold fish.

This species was introduced into England about the year 1691. It breeds freely in the open waters: in Scotland it does not increase.

In the preceding list of our native fishes, we have purposely omitted a few spurious species which have a place in some of the works on British zoology. Perhaps one or two in the present list may, upon farther inquiry, be found mere varieties. This, we suspect, will prove to be the case with some of the species of the genera Squalus, Raja, Salmo, and perhaps Cyprinus.

ICOLMKILL, or I-COLUMB-KILL. See IONA.

ICOSANDRIA. See BOTANY.

IDA. See TROY and TROAD.

IDAAN, a race of mankind dispersed through several islands of the Eastern seas, and principally characterized by the singularity of their customs. Mr Dalrymple justly observes that "the Idaan of different places go under different denominations, and have different languages," and accordingly we find them under the name of Idaan, Maroot, Alforese, Horaforas, Dejakkese, Biadjoos, and Oraa-Abing. All these seem to constitute but a single race of people, but the appellation Idaan is more specially applicable to those in the northern parts of Borneo; Alforese to those of the Molucca islands, now nearly extirpated from some of them; and Horaforas to those of the eastern islands in general. See BORNEO, Vol. III. p. 729.

IDEAL BEAUTY. See TASTE.

IDENTITY. See LOGIC.

IDOLATRY. See POLYTHEISM.

IDRIA, is a district of Carniola, dependent on the circle of Adlerberg, in the dominions of the emperor of Austria. Having been wrested from that monarch by the French in 1809, it was constituted a canton and mayoralty, extending over eleven miles square, and forming part of the Illyrian provinces. It was further subdivided into the town of Idria, the village of Lower Idria, and eight hamlets. The whole of this territory is mountainous, and interspersed with narrow vallies, which are copiously watered by torrents from the hills. The river Idrixa rises in the Julian Alps, about three leagues from the town of Idria, and after receiving the Canomla, Zalla, and several subterraneous streams, it falls into the Isonzo, 19 leagues lower down. This river abounds with fish, among which are fine trout of remarkable size. Several sluices and canals are formed in the valley where it runs, one of which, of superior construction, was executed by the French in 1813, on the torrent Woitschaik, for the purpose of floating wood.

Climate.

Thunder storms prevail in summer, and there are sometimes two or three in a day: the heat is then oppressive, owing to the reflexion of the sun from the surrounding hills: autumn is rainy, and winter is of long duration. The thermometer in the most severe cold falls a few degrees below zero. Two chains of mountains 1728 feet high, bounding the valley of the Idria, are covered with snow nearly six months of the year: and 300 or 400 men are employed while storms prevail, clearing the great road to Laybach. The medium height of the barometer is 27 inches 5 lines; its variations are neither frequent nor considerable. A strong prejudice subsists in the country regarding the insalubrity of the climate, which of late has been controverted. But although two thirds of the district are forests, vegetable life is languid in the immediate vicinity of the town of Idria; fruits and grain seldom ripen, and cattle always decline. Tooth-ach is universal among the inhabitants, few persons have good teeth, and they are lost by all at an early age. As the inhabitants are principally divided into miners and forresters, the one class enjoys vigorous health, while the other is subjected to disease: and the consequences are beheld even in their respective offspring. Life is here of short duration; many die young, and forty is an age beyond which great expectations of survivance are not entertained. The unusual insalubrity of Idria is traced to the mines and metallurgic operations, by those who consider the atmosphere of the same constitution as in other places.

Mineralogy.

The minerals of Idria are in considerable number and variety, and also of uncommon value compared with their narrow bounds. Among these are white marble, found in the valley of the Canomla; thick beds of different coloured jasper in the country of Woiska; fine and coarse free stone; sulphuretted iron and indications of coal.

Quicksilver mines.

But the chief riches of Idria are its quicksilver mines, the largest, most magnificent, and most productive in the world. The metallic stratum is situated about 240 yards deep; it extends 800 yards in one direction by 1000 in another: and lies in a valley, whose surface is 507 feet above the level of the sea. Six shafts penetrate the mine, four of which are vertical, and two have an inclination. The former are named St Barba, St Theresa, St Francis, and the Emperor Joseph; three of them are appropriated for the extraction of the mineral substances, or discharging water, which is accomplished by 15 pumps, worked by a hydraulic wheel 36 feet in diameter; while the fourth is reserved for introducing the materials necessary for the operations below. Access is gained from within a spacious building, situated in the town of Idria, leading almost horizontally under a lofty vault to a staircase, always kept in excellent repair, constructed mostly of stone steps, but partly of wood. It reaches to the depth of 150 yards, after which the remainder of the descent is accomplished by wooden ladders, which are sometimes damp, and on that account less convenient and agreeable. Dr Brown observes, that in leaving the mine, he ascended by a ladder of 639 staves. There are several landing places paved with flag stones in the course of the descent, and benches to rest upon: and the whole mine is kept remarkably clean and in good order. The subterraneous excavations are occupied by nine horizontal galleries, including intermediate ones, with their numerous ramifications, about seven feet high, and as much in width. They are arched over by artificial building, unless where they penetrate the solid rock, which requires no support, and are in general well aired from currents being established between them. According to Jars, by whom the mine was visited about the year 1759, the entrance to the principal gallery is covered by an iron grating, at the moment the workmen descend, which is kept down until their return. At the distance of 260 yards from the mouth of the same gallery, there is a chapel where mass is performed on all festival days, and the images of saints, protected by a grating, stand in niches. Kuttner says the principal shaft is 86 fathoms in depth, and Keysler, that the lowest part of the mine lies 840 below the surface of the earth. The temperature of some parts is such as to cause profuse perspiration in the workmen: numerous thermometrical observations prove, that among great beds of rich ores, the heat is from 80° to 95°. Every thing within seems to announce disorder and chaotic confusion: the whole mineral kingdom apparently has been confounded by some catastrophe, to constitute the treasures which this spacious cavern contains. Enormous heaps of shells are intermixed with mercury, bitumen, and sulphur, and the ores are disseminated in the most unequal manner. On account of its uncommon arrangement, the mine of Idria bears no resemblance to any other, and presents none of those facilities in the working which are found in mines with veins.

Considerable misapprehension seems to have prevailed concerning the quality of the ores of Idria. Some authors have affirmed, that it contains 50 per cent. of metal at an average, and that portions afford even 80 per cent. But the mean produce of 9908 tons was only 8.616 per cent. by exact observation. Virgin mercury, as we have seen in the preceding list of combinations, exists in various situations, elaborated exclusively by the hand of nature. It appears in pure globules, and has been known to issue in a slender stream from some narrow fissure in the rocks. A miner is said to have collected 36 pounds of mercury in this manner in six hours. The quantity of virgin mercury procured annually is very unequal. When Dr Pope visited the mines in 1663, it amounted to 11,862 pounds, which nearly doubled the product of 1661, and somewhat exceeds the statement of Keysler and Jars, at 100 quintals, or 10,000 lib. Probably it is more rare at present. A small portion is always presented in a leathern purse to foreigners of distinction who inspect the mines.

Extraction of the metal.

The ores being separated, according to their quality, by the miners, are drawn up in strong square boxes, each capable of containing 700 or 800 lib. by means of a hydraulic wheel put in motion by the water of a canal led from the Idrixa. All are then conveyed to the lavatories, or washing rooms, where they undergo a new assorting, and the richer kinds are set apart by themselves. The object of washing is to disengage all the earth which contains no mercury; and for this purpose seven wire sieves are first employed, and the result then transferred to another set of very expert workmen. Sieves suspended in a cistern, and, while immersed, kept in constant motion, are now used, that the heaviest particles may fall to the bottom; and great care is taken to preserve those of a red colour, as they contain cinnabar. After these two levigations the ores are pounded, and again carried to the lavatories to undergo a third on inclined planes. From the lavatories they are conveyed to furnaces to be subjected to distillation; but, before being exposed to the action of the fire, the whole are rigorously assayed, in order to anticipate what product may reasonably be expected. As there are two kinds of ore, one in large pieces and the other in powder, there is a furnace for each. The furnace destined to receive the first has two fire-places and four chambers or ovens, which communicate by lateral conduits with two rows of reservoirs, or very high chambers of mason-work, separated by intermediate walls, but mutually communicating by means of alternate apertures a foot square. Of these reservoirs or condensers there are twenty-eight. The second furnace, appropriated for burning the ores in powder, has six furnaces and twenty-four chambers, instead of twenty-eight. The area in both is inclined to facilitate the flowing of the mercury, and a conduit common to the whole condensers brings the mercury into another great reservoir, where it is collected for use. The charge of the first furnace is 30,000 lib. of ore, that of the second 60,000. When the furnaces are charged, all their apertures, and those of the condensing chambers, are carefully luted with clay and slacked lime. The fire is then progressively augmented during nine hours, until the earthen clods, wherein pieces of ore or the powder have been put, become red hot, and the ores burn vehemently. The whole is then allowed to cool for six days, and the mercury, completely disengaged, is collected in the general reservoir. As the heat of the furnace, particularly of that which burns the larger pieces, is retained a long time, it would be difficult to collect the metal sooner. A single charge of the furnaces will frequently produce 8000 pounds of quicksilver. The mercury is taken out of the common reservoir, and packed in white sheep-skin bags, which have been tanned with alum, in quantities of 25, 50, or 100 pounds. The bags are then conveyed to a magazine, where each is covered by a second skin, and packed up in casks, which are exported to the various places where they are required.

Mercurial preparations.

But, independent of the pure mercury thus obtained, and exported from Idria, there are mercurial preparations to a very great extent of all the different kinds which are known in commerce. With the exception of Chinese vermilion, the products seem scarcely susceptible of improvement. For these purposes there is a spacious building, divided into three great laboratories. The first is appropriated for amalgamation of sulphur and mercury, which is then converted to cinnabar; the second is consecrated to the preparation of vermilion, wherein eight mills are employed in grinding the cinnabar; and in the third there are twenty-two furnaces, each provided with six large iron capsules. Much accessory apparatus is used besides.

In addition, and subsidiary to the mining establishment, and that for mercurial preparations at Idria, there are several branches of arts and manufactures. These consist chiefly of a glass work, for providing the bottles and window glass; a pottery for all the earthen ware required; a tannery for preparing the leather packages; and a rope work which furnishes cordage. Numerous mechanics, and artisans of all descriptions, are also ready to provide the necessary apparatus for the various operations.

Produce of the mines.

As the mines of Idria are the most productive which are known, it may not be uninteresting to learn the quantity of metal obtained from them. It has been different at different periods, which is not surprizing, considering the uncertainty which attend subterraneous researches. In the year 1663, they produced 255,981 pounds. About the year 1730, the quantity seems to have been 360,000; twenty years later it was calculated at 300,000; and in the year 1799, Kuttner was informed that the product has been known to amount to 1,000,000 or 1,200,000 pounds, which is probably erroneous. But by an accurate computation made by the director of the mines under the French regime between the years 1809 and 1813, we learn that the average quantity obtained yearly in that time amounted to about 365,928 pounds. Of the total product, there were delivered into the magazines the following proportions in quintals of 100 pounds each.

Mercury	14,194 quintals	25 lib.
Cinnabar	702	25
Vermilion	2,700	29
Corrosive sublimate . .	24	50
Calomel	64	—
Red precipitate	28	67
	17,713	96

The whole of this was obtained in 56 months. Thus the profits of the mines, which are the property of the Emperor of Austria, and carried on at his expense, are very considerable; being at a medium about 800,000 francs, or £35,000 Sterling yearly. To render the average nearly the same, the rich and poor ores are worked at once.

A great quantity of the quicksilver was formerly exported to Spain, and from thence to South America, where it was employed in the separation of the metal in the silver mines. The Dutch were accustomed to purchase 100,000 lib. yearly. Most part of it is now carried to Vienna, and a large proportion to England.

In the year 1663, there were 280 miners, but at present 700 are employed, besides 300 wood cutters, who are under an inspector general; and there are nearly 600 pensioners, including women and children. The whole of this great establishment is under the most admirable system of administration. All the workmen are divided into companies; they assemble at three in the morning, when their names are called over, and they descend into the mine, each with a lamp in his hand. Owing to the high temperature of the galleries, the rarefaction of the air, and evolution of certain gasses in the combustion of the lamps, as well as the deleterious effluvia escaping from the metals, their health suffers severely. Those who are occupied where native mercury is found, inhale small particles of it, and very soon lose their teeth; those employed in sweeping the chambers of condensation also inspire a considerable quantity of metal while detaching it from the sides of the condensers. Thus they undergo a copious salivation. "We saw there," says Dr Pope, "a man who had not been in the mines above half a year before, so full of mercury, that putting a piece of brass in his mouth, or rubbing it in his fingers, it immediately became white like silver. I mean it had the same effect as if he had rubbed mercury upon it. And so paralytic, that he could not, with both his hands, convey a glass half full of wine to his mouth, without spilling it, though he loved it too well to throw it away." Some observers affirm, that the quicksilver insinuates itself into the bodies of those who work the virgin mercury, so that when they go into the warm bath, or are put into a profuse sweat by steam, drops of pure mercury have been known to issue through the pores from all parts of their bodies. This much is certain, however, that the workmen who have been occupied several years in the furnaces, become subject to shiverings, convulsions, decrepitude, and a premature old age. Their wages, partly in grain, and partly in money, are exceedingly moderate; but by the paternal care of government, all are provided with a competency when they are unable to continue their labours.

History.

The quicksilver mine of Idria was accidentally discovered in the year 1497, by a peasant, while receiving the water of a spring into a tub for the purpose of trying if it was tight. He was astonished on emptying its contents to find some metallic globules at the bottom, which he immediately ascribed to witchcraft. But having conquered his apprehensions, he collected them together for the inspection of a goldsmith in the small town of Bischoflaach, about four leagues distant. Neither promises nor presents, however, could induce him to point out the spot; and he engaged another peasant, Cazian Anderlin, to assist him in working the mine. But soon ceasing to find native mercury, their labours were abandoned. Other peasants followed in their footsteps, and were equally disappointed. A company of miners nevertheless had better success. In 1525, the works were interrupted, and the miners totally ruined by an earthquake; nor was the pursuit resumed with activity until 1572. The Archduke Charles of Austria having taken possession of the mines, established a regular system for their management. Vast quantities of mercury were extracted from them; and their riches, together with their great extent, attracted the notice of the curious from all parts of the world. In 1803, a fire broke out in the mine, which did great damage, and occasioned the loss of several lives; but it was observed, that the subterraneous temperature was lower, and that the air of certain galleries was less easily vitiated than before. The French extorted the cession of Idria in 1809, and worked the mine for behoof of the order of the *three golden fleeces*. Numerous and important improvements were made by them, until the Emperor of Austria regained possession of it in 1813.

Town of Idria.

Immediately above the site of the mines the town of Idria is built, spreading over the valley, and up the sides of the hills. All the houses are detached; they are small; but each is inhabited by two or three families, and has a piece of ground from which the owners endeavour to raise a few vegetables. Though irregularly built, its aspect is not unpleasant to the eye, and it exhibits none of that black and dismal appearance which is common to towns in the vicinity of mines. Its principal public buildings are, a handsome parish church; a very fine hospital, to which two physicians and a surgeon are attached; and a dispensary for supplying medicines to the sick. There is a public school for the education of youth, with six masters, and a female to superintend that of girls. An old castle contains the treasure for the necessary expenditure, and a magazine for storing up the products of the mine; also one for provisions to the inhabitants; several public offices, as a hall for the council of administration, and accommodation for its chief director. Some of the edifices devoted to public purposes were erected here during the occupation of Idria by the French. In the year 1812, the population of the town amounted to 4095, and that of the whole district to 7060. Lat. 46° 16′ W.; Long. 33° 53′ E. Distant 18 miles from Upper Laybach. See *Philosophical Transactions*, vol. i. iv.; Brown's *Travels*, p. 83; Kuttner's *Travels*; Jar's *Voyages Metallurgiques*, tom. ii.; Keysler's *Travels*, vol. ii. (*c*)

JEDBURGH, a burgh town of Scotland, and the principal town of the county of Roxburgh, is pleasantly situated on a declivity on the north side of the river Jed. From historical evidence, it appears that a village, castle and church, had been founded at New Jedworth, now called Jedburgh, before the middle of the ninth century.* As Roxburgh, originally the principal town of the county, was often possessed by the English, and the village reduced to ruins by the frequent sieges of the castle, the seat of the judicatories was transferred to Jedburgh after the reign of David the First. The natural beauty of its situation, as well as its vicinity to the borders, attracted the frequent residence of some of the princes and persons of high distinction in both nations, as the town occasionally fell into the hands of the English or the Scots. Here the pious David founded, or, according to the opinion of some historians, rebuilt, A. D. 1138, a monastery, which he dedicated to the holy Virgin, and appropriated to canons regular of the order of St Augustin, imported from Beauvais in France. A church had been erected at Jedburgh during the Saxon period, in the ninth century; and, as the lower storey and gable wall of the monastery still remaining, exhibit beautiful specimens of the Saxon architecture, it affords a strong presumption of their remote antiquity.† Great additions, during successive ages, were made to the revenue of the abbots and monks, by the liberal donations of the heirs of the throne, and of opulent barons and individuals belonging to both kingdoms. Before the expiration of the 12th century, the churches of Ancrum, Longnewton, Oxnam, Eckford, Crailing, Nisbet, Hobkirk, Liddel or Castleton, had all become the property of the abbey of Jedburgh; and various accommodations of fuel, fish, &c. were also acquired in distant districts of the country. The increasing emoluments of the monastery of Jedburgh were beheld with a jealous eye by the bishops of Glasgow, to whose diocese it belonged, and occasioned frequent disputes and litigation between them and the abbots, which were at length terminated by the interposition of royal authority.‡ A convent of Carmelites was founded at Jedburgh by the donations of the citizens and neighbouring inhabitants in 1513, which gives colour to a conjecture, that the constant rage of hostile incursions from the neighbouring kingdom did not intrude upon the tranquillity of religious communities, and that even the savage spirit of the border warriors was overawed by a reverence for superstitious pageantry, and the display of consecrated grandeur. The names of all the streets and closes in the town of Jedburgh, and of the adjacent fields, denote the ancient occupancy and predominance of the ecclesiastical orders; Canongate, Abbot's Tower, Abbey Close, Dean's Close, Friars, Prior Meadow, Monklaw, Virgin, Ladysyards, &c. A part of the ruins of the Abbot's Tower, at the head of the Abbey Close, and of the castle, on the hill at the west entrance to the town, have been lately removed. The only building of antiquity now remaining, with the exception of the abbey, is a house at the bottom of the town, celebrated on account of its having been the residence of Queen Mary, October 1566, when she held a justice court at Jedburgh, and from whence she made a visit to Bothwell at his house in Liddisdale, distant from Jedburgh 17 Scots miles, and returned the same day.

All the lands, baronies, and estates, vested in the Abbey of Jedburgh, were conferred by James VI.

---

* It was called New Jedworth, as distinguished from Old Jedworth, five miles south, and nearer the English border.

† See CIVIL ARCHITECTURE, Plate CLXVII.

‡ The bishop of Durham claimed a right to Roxburghshire as a part of his diocese, ascertained and acknowledged by ancient treaties between the kings of England and Scotland.

1662, on Sir Andrew Kerr of Fairnieherst, and converted into a temporal lordship, together with the title of Lord Jedburgh.*

It is to be regretted, that the superstitious veneration, which in barbarous ages had protected the religious edifices, lost all its influence on the Protestant reformers, whether of warlike or ecclesiastical characters. The abbey, as well as the town of Jedburgh, was burnt and demolished by Lord Surrey, 1523, on his second incursion into Scotland. But, as has been observed, the ground or lower parts of the monastery escaped devastation at that time, nor did it afterwards sustain any damage from the fanatical rancour of domestic reformers. Jedburgh has the honour of parochial precedency, being the oldest parish in Scotland of which any historical record has been transmitted to posterity.

As Jedburgh was exposed to frequent depredations from the incursions of the English, and the greatest proportion of the property and all authority were engrossed by the ecclesiastical dignitaries, it does not appear to have made any progress in the manufactures and commerce, which, previous to the Reformation, began to be cultivated, in a limited degree, by several of the towns and burghs removed from the scene of rapine. In the estimate of the revenue of the burghs for fixing the assessment of tax for the defence of the borders, in the minority of Queen Mary, Jedburgh stands perhaps lower in the list than any one of the same population and extent.

After the union of the crowns, when free intercourse was opened between England and Scotland, the town of Jedburgh derived great profit, and attained a considerable degree of commercial prosperity, from the exportation of salt, skins, and malt, into the neighbouring county of Northumberland, and carrying wool to the coast towns, to be thence exported to the continent. This contraband traffic continued for many years after the union of the legislatures, till it was checked by the exaction of the malt tax 1728, and the more unrelaxed vigilance of excise officers on the English borders. From this period, the population and industry of the town of Jedburgh underwent a rapid decline. Efforts were made, from time to time, by some of the neighbouring gentlemen, and by the wiser citizens, to set on foot different branches of manufacture. A linen company was established. The manufacture of coarse wools was also attempted, but, from the discontinuance of these speculations, they appear to have disappointed the expectations of their patrons. The delusive hope of acquiring indolent independence, as the price of political service, and party contests and divisions, repeatedly occasioned by the return of elections after the union of the legislatures, deadened the spirit of enterprize, and retarded the occupation and improvement of those local advantages, which, in later years, have so much redounded to the credit and melioration of the community.†

About fifty years ago, a few enterprising individuals began to carry on a considerable manufacture of flannels, blankets, and coarser woollen fabrics. Their success roused the emulation of their fellow-citizens. A spirit of industry pervaded all ranks; and a great variety of woollen manufactures were pursued with dexterity and profit. During this period of industry, the wages of labourers have been doubled. There has been no want of employment for any class of men. Shops have been multiplied, and better furnished; and the surrounding fields brought to the most perfect state of culture. In the course of ten years preceding the year 1816, several hundreds have been added to the population of the town of Jedburgh, and more money has been expended in building and improvements of every kind than for forty years preceding.‡ Land in the vicinity of Jedburgh was then seldom purchased at more than £20 pounds per acre, and a few years ago it has been sold for £100, and £150 per acre. The rent of the surrounding inclosures has been raised from 10s. and 20s. to £5, and, in some instances, to £6 or £7 per acre. This description of the prosperity of Jedburgh must, however, be understood to refer to a period preceding the year 1816, when, from obvious reasons, which need not be mentioned, every species of manufacture and labour began gradually to slacken, and more than two-thirds of the persons employed are now laid aside from work. A great proportion of the fields, surrounding the town, had been purchased by the successive heirs of the Lothian family; but, as these made no part of the entailed estate, they were sold in separate lots, about twenty years ago, to private individuals, who are inhabitants of the town.

After the Reformation, Roxburghshire was consigned to the diocese of the bishop of Glasgow, and Jedburgh was then, and still continues to be, the seat of the presbytery. The parish is of great extent, reaching from the river Teviot to the borders of Northumberland.

The total population of the parish was found, upon the late survey in 1813, to amount to 4927, of which 2827 reside within the royalty of the burgh. The males in the town 1354. Females 1473.

There are, besides the parochial church, three dissenting meeting-houses, all attended by large congregations. The parish church, consisting of the western division of the abbey, was repaired in 1792, and adapted, with great taste and propriety, to the style of the ancient edifice; and may be considered as one of the most elegant churches in the kingdom. The grammar and English schools, the former in the patronage of the heritors, the latter in the patronage of the magistrates, are now united, and conducted with great success by the present incumbent Mr Robison.

The set of the burgh is nearly the same as that of Edinburgh, consisting of a provost, four bailies, dean of guild, and treasurer; eight deacons of the trades; and fourteen merchant councillors. The revenue of the burgh arises entirely from the rent of the mills, to which the inhabitants of the town are thirled, and from the customs upon meal, barley, &c. imported into the town for sale. The magistrates of Jedburgh preside, together with the chamberlain of the Duke of

---

* The Marquis of Lothian is the male representative of this ancient family, and his ancestors sat as peers in the Scotch Parliament, with the title of Lord Jedburgh.

† The situation of Jedburgh is well calculated for the manufacturing of woollen goods, being situated on a river, affording a variety of convenient situations and falls for mills. From the vicinity of Cheviot hills, any quantity of Cheviot wool may be procured and laid down by the farmer, free of any expense for carriage. If the manufacture of worsted goods or English blankets is preferred, an abundant supply of Leicester wool, with the same advantage, can be procured from the stock farms on the lower grounds. In the year 1815, one hundred and four persons were employed in the manufacture of coarse woollen cloth, Scotch blankets, baize of different colours, flannels, &c. and 205 were employed in the lamb wool hosiery.

‡ In the year 1773, the whole population of Jedburgh amounted to nearly 2000, and now amounts to 2827. Within the last forty years, six bridges have been built within less than three miles of the town, three of them immediately contiguous. A magnificent court-house was erected eight years ago in the middle of the town, and adds to the beauty of the streets. An asylum is also provided for the reception of persons deranged. Persons convicted of crimes are also confined in it to hard labour.

Roxburgh, at St James's fair in the vicinity of Kelso, and enjoy the half of the customs; privileges which redound more to their honour than profit, as they are supposed to have been conferred as a reward for meritorious services during the period of the Border wars, but are not productive of any solid emolument. There are four fairs held annually in the town of Jedburgh The whole revenue of the town does not exceed £500 per annum, of which a large part is expended annually for the interest of debt. The mills were formerly included in the lordship of Jedburgh, conferred on Sir Andrew Kerr; but were afterwards transferred, either gratuitously or for a small sum, to the burgh, and confirmed by a charter of James the First.

The poor of the town are maintained by an assessment, laid upon the inhabitants in proportion to the value of their houses and landed property within the royalty. The number of poor now in the list of supply amounts to 67, and the assessment granted for the last half year, (July 1817) to the sum of £135. The annual rent of the houses and gardens within the royalty is estimated at £4000. A parish bank was established July 1815 in the town of Jedburgh, in partnership with the country parish, and six neighbouring parishes, which has fully answered the hopes of its patrons; the small sums deposited now amounting, July 1817, to £1996. An auxiliary bible society was established two years ago, under the direction of the most respectable, neighbouring gentlemen, and the ministers of the town. A branch of the British Linen Company was established at Jedburgh in the year 1791, and carries on business to a great extent.

There is a good butcher market in the town of Jedburgh; the bread has been long excellent; and in the summer months, and in winter when the weather is mild, the town is well supplied with fish, brought from the distance of thirty miles A stage-coach runs from Jedburgh three days in the week, and returns in the alternate days. A coach also runs from Hawick to Berwick, which passes through Jedburgh and returns the same day. The greatest grievance to which the town and neighbourhood are subjected arises from the dearness of fuel, consisting chiefly of coals brought from Northumberland. The average price may be stated at 1s. 7d. per cwt.

The diversity of surface, and the adjacent woods and brooks, afford a variety of beautiful picturesque scenes. The soil is deep and fertile even to the top of the hills, and peculiarly favourable to horticulture and orchards, for which Jedburgh has been long celebrated. Some of the pear-trees, which bear the marks of great antiquity, are supposed to have been planted by the hands of ecclesiastical proprietors before the Reformation.*

JEDO. See Jidda.

JEJURRY is the name of a pretty large Mahratta town in India in the province of Bejapoor. It is principally celebrated for its temple, dedicated to an incarnation of Mahadeva, or Siva. It is built of fine stone, and has a very majestic appearance and situation, on a high hill, in a beautiful country. The ascent to the temple is by a handsome flight of broad stone steps, arches being in many places thrown across over the stairs. The inner temple where the deity is placed is ancient and not very handsome. The establishment of dancing girls attached to it, amounted in 1792 to 250. The revenues of the temple are derived from offerings, and from houses and lands given by pious persons. The annual expenditure on account of the idol is £6000. The idol has horses and elephants kept for him, and along with his spouse, is bathed daily in rice and Ganges water, the last of which is brought from a distance of 1000 miles. At the annual fair which is held in January, no fewer than 100,000 persons visit Jejurry. East Long. 74° 17′, and North Lat. 30° 54′. See Moor's *Hindoo Pantheon*.

JELLY. See Chemistry, Vol. VI. p. 130.

JEROM, or Hieronymus, was born about the year 329 at Strido, a town on the confines of Pannonia and Dalmatia. His father, who was a person of rank and property, took great care of his education; and sent him at a proper age to study at Rome, under the best masters of those times. Under the celebrated Donatus, he made great progress in the belles lettres, and all the learned languages; and was particularly careful to accomplish himself in the art of oratory, that he might the better recommend the Christian tenets. Having finished his education at Rome, he travelled into various countries in pursuit of knowledge, examining all the public libraries, and conversing with all the men of learning in his way. Upon his return to Rome, he resolved to devote his future life to study, and to withdraw himself entirely to some remote region, at a distance from large towns and civilized life. Taking with him only his books, and money sufficient to defray the expense of his journey, he proceeded through Asia Minor to Jerusalem; thence to Antioch, where he had a dangerous illness; and finally settled in a frightful desert of Syria, where he entered upon a strict monastic course of life, in the 31st year of his age. He applied himself especially with the utmost assiduity to the study of the sacred scriptures, and of the oriental languages; but, after four years of laborious application, his health became so much impaired, that he found it necessary to return to Antioch. By Paulinus, bishop of that city, he was ordained a priest in the year 378; but with the express stipulation on his part, that he should not be confined to any particular cure. In 381, he went to Constantinople, where he acknowledges himself to have received much valuable instruction relating to the Scriptures from Gregory Nazianzen; and, in the following year, he accompanied Paulinus of Antioch to Rome, where he became secretary to Pope Damasus. After the death of that pontiff in 385, and in consequence of the vexations which he experienced from the followers of Origen, he again removed from the city of Rome, and took up his abode at Bethlehem in Judea. Thither he was followed by many persons of both sexes from various parts, who had resolved to embrace the monastic life, and who were attracted by his fame for learning and piety to put themselves under his superintendence. Here he enjoyed all that repose in which he so much delighted, and employed the remainder of his life in composing a variety of learned works, and in diligently attending to the religious instruction of those who had collected around him as their pastor. He was much engaged particularly in writing against the prevailing heresies of his time, especially against the errors of Origen, and those who supported the tenets of that rival father. He lived to the age of 90 years, retaining his vigour of mind to the last; and died on the 30th of September, A. D. 420. He has been pronounced by Erasmus, "the greatest scholar, the greatest orator, and the greatest divine, that Christianity had then produced;" but Le Clerc professes to shew, that his eloquence is often the most hyperbolical declamation, his acquaintance with the learned languages far from accurate, and his reasonings generally obscure and inconsistent. His style as a writer, is nevertheless acknowledged to be in no small degree both elegant and animated; and his judgment and learning to have been upon the whole

---

* The Editor is indebted for this article to Thomas Somerville, D.D. F.R.S.E.

superior to those of any of the fathers who preceded him. His talents were better than his temper; and he made greater attainments in the knowledge than in the spirit of Christianity. He was a man of the most choleric disposition, and ready to burst into the most outrageous abuse upon the slightest provocation; insatiably greedy of fame, and bitterly censorious of his most respectable rivals and opponents. The first edition of his works was published by Erasmus at Basle in 1526, with an account of his life prefixed; but the latest and fullest was published at Verona by Vallersius, in 11 vols. folio. They consist chiefly of his Latin version of the scripture, distinguished by the name of the Vulgate, commentaries on different books of scripture, polemical treatises, letters, and biographical accounts of preceding ecclesiastical authors. Of these, the commentaries and letters are accounted the most useful, and the chief advantage of his writings consists in the information which they afford respecting the opinions of the learned Jews in biblical literature, and the fragments which they contain of the ancient Greek translations of the Bible. See Mosheim's *Ch. Hist.* vol. i.; Lardner's *Works*, vol. ii.; Milner's *Ch. Hist.* vol. iii.; Cave's *Hist. Liter.* vol. ii.; Le Clerc's *Questiones Hieronymianæ*; and Jortin's *Remarks on Eccl. Hist.* (*q*)

Climate.

JERSEY, is an island in the English Channel, subject to the dominion of Great Britain, lying off the coast of Normandy in France. Its form is an irregular parallelogram, the extreme length of which is 12 miles, the extreme breadth 7, and the superficial area 62½ square miles, or 40,000 acres. The climate is so mild, that frost is rarely of any duration, and snow seldom lies above two or three days in winter. Shrubs requiring shelter in the southern parts of England, sustain no injury here from exposure, and spring flowers blow in the open air of the colder season. Fogs are not uncommon, and there are frequent gales, together with keen and penetrating winds from the east, which are severe on delicate constitutions. Pulmonary affections are often fatal, and there are numerous cases of scrophula, which some have ascribed to the habitual use of salted provisions.

The surface of Jersey is an inclined plane, rising abruptly from the sea on the north, where its lofty cliffs are in general 100, or frequently 200 feet high, and declining gradually to the southern coast. Its shore is deeply indented by many fine bays, of which St Aubin, Brelade, de Lecq, and Boulay, are the most important. But they are not well sheltered from storms, and the ports of St Helier and St Aubin are both dry at low water. A chain of rocks runs out from the north and north-east, dangerous to mariners, as are the shallows in other parts; and the tides, which rise from 40 to 50 feet, exhibit some singular phenomena.

The island is watered by numerous streams, and so copiously, that it has been observed, there is scarcely a house which has not a spring or a brook near it. All the mineral waters hitherto discovered are chalybeate; but only two have attracted any notice on account of their medicinal properties—one in the parish of St Mary, the other in that of St Saviour.

Mineralogy.

A large portion of Jersey consists of sienite, especially the northern coast, where there are rocks of various elevation, generally exhibiting broad and perpendicular faces to the sea, and every where intersected by veins also perpendicular running north and south. Many remarkable caverns have been formed in them by the action of the waves. What approaches nearest to granite is quarried at Mont Mado, of which ample use is made for architectural purposes. Varieties equally hard and compact are obtained at St. Brelade's Bay and Plemont. These of sienite appear in some places to pass into porphyry, in others into a kind of green stone in a state of partial or entire decomposition. No metallic traces, except of iron and manganese, are seen in any part of Jersey. It has been said that copper ore is found. Ochre of different colours is obtained in various places, and there are some specimens of tripoli.

Vegetable produce.

The surface of the island is extremely irregular, consisting of numerous small vallies running across the island; and the soil, which is principally a light and fertile earth, has been compared to that of Guernsey. Considerable variety of vegetables is produced here. Madder grows wild, also the luteola, single chamomile, and a number of aromatic herbs. Laver and samphire grow on the coast, and chiefly to the north. Fine fruits of the highest flavour come to maturity in the orchards. A kind of pear called *chaumentelle* is particularly celebrated, some attaining a pound in weight. It sells for a high price at all times, and is sent in presents to England. From the profusion of apples a great quantity of cider is obtained yearly. There are no woods of forest trees throughout the island; but one of the most important vegetables is sea weed, or *vraic*, which grows all around the rocky shore, and is used, either in a recent state for manuring the land, or when dried, as fuel. Only two seasons in the year, which are proclaimed by order of the magistrates, being appointed for cutting it, whole families watch the period when it is torn off the rocks by tempests, to rake it together. The ordinary farinaceous grain of England is cultivated: also bearded wheat, called *froment tremais* in Jersey, which is reaped in three months, and the various edible roots. Lucern and clover are in general cultivation, but hops have not succeeded. Instead of reserving a field for each kind of grain, it is common to sow several in patches in those of very small size. The vegetable produce of the island is considerably less than its consumption; and there is sometimes a temporary scarcity in the town of St. Helier, extending both to bread and meat.

Animals.

Many species of fish frequent the shores, but the inhabitants do not seem to avail themselves of the great advantage to be derived from them. Rays, turbot, plaise, soles, and mullet are caught, besides others. "But," in the words of an old author, "the sea about Jersey may be stiled the kingdom of congers," which are seen among the rocks at all seasons; some six feet long, and weighing 54 pounds. Oysters, lobsters, and crabs, are plentiful. Numbers of small snakes, all harmless, and also beautiful lizards, are seen on the island. It is infested by toads of monstrous size, though none are found on Guernsey. The red legged partridge was once common, but is now nearly extirpated. There are three species of field mice, one of which, in as far as we can learn, is the *mus* typhlus, or blind mole, hitherto ascribed to southern Russia. It approaches to the size of a rat, and is of a grey colour, with long hair: the eyes are so small as to be scarcely discernible; and under the fur there are in the site of the ears two bare vesicles. The horses of the island are small, strong, and hardy; and the cows are of that breed known in England by the name of Alderney cows. Sheep are diminutive in size, and mostly black. Another species is alluded to by authors of the seventeenth century, as "those famous sheep with six horns, three of each side; one whereof bent towards the nose, another backwards towards the neck, and the third stood erected upwards in the midst of the other two, mentioned by writers as one of the singularities of this island, are become very rare." Some goats are bred; and hares are scarce.

Inhabitants.

The inhabitants are distinguished by few peculiarities from those of the rest of the British dominions, except in their language, which is French. This is the vernacular tongue; divine service, pleadings in court, and the public acts, are all in good French, which is understood, and occasionally spoken, by the upper ranks; but, in compliance with custom, they frequently converse in the provincial language, which is described as consisting of more dialects than those of ancient Greece. But English is becoming more prevalent daily, and, if it received greater encouragement, would soon be universal.

Towns.

In the year 1806, the total population of Jersey amounted to 4363 families, consisting of 10,284 males and 12,571 females, being 22,855 souls, which is at the rate of 365 persons to each square mile. These are dispersed in twelve parishes, containing two towns, several villages, and several fortresses. The town of St. Helier is the capital, situated on the east side of St. Aubin's Bay, and consisting of about 1000 houses, wherein between a third and a fourth of the whole population, or above 6000 individuals, reside. In the year 1693, it seems to have consisted of only 210 houses. Their antique appearance is now modernized; many of the streets have footpaths, but they are liable to be overflowed by the channels of a stream from the north, and the town is not yet lighted; consequently, a great number of small lanterns are seen in motion at night. There is a square, wherein stands a gilt statue of King George II. in Roman costume, surrounded by a neat iron railing. The parish church, which is the most modern in the island, was built in 1341; but, since that time, it has undergone considerable alterations. It contains a neat organ, and some handsome mural monuments. There are also chapels for Presbyterians and Wesleyan Methodists, both of which are neat and spacious buildings of recent erection. The Roman Catholics perform divine worship in a private apartment, not being sufficiently affluent to erect an edifice exclusively devoted to the exercise of their religion. There are a workhouse and a public hospital here for the use of the whole island. The latter was rebuilt in 1783, in consequence of another being damaged by an explosion of gunpowder. It has commonly about 100 patients, of whom not above two-thirds are natives of Jersey, and about a tenth part of the whole labour under mental derangement. On one side of the square is the court-house, a plain but solid structure, wherein are held the assembly of the states and the courts of judicature; and the governor of the island has a house and garden belonging to the town. A new prison, situated at the west extremity of St. Heliers, on the sea shore, was completed in 1815. The basement of this edifice has a squared front of sienite from Mont Mado, and is separated from the upper story by a fascia of dark grey granite from Sorel, a rocky promontory in the northern quarter of the island. Above this the sienite is resumed; and the uniformity being relieved by pilasters between every window, the whole is completed with an elegant cornice of Portland stone. The front stands on an arcade extending 120 feet in length by 8 in width; and the intercolumnations are grated to the crown of the arches. The space within the arcade is for the accommodation of the male prisoners, when they leave their dormitories. Water is raised to a capacious cistern in the roof, by means of a forcing pump, and the prisoners of every description have access to a constant and ample supply. The centre of the upper floor forms a chapel, divided by partitions of sufficient height, to prevent any communication whatever, whither the prisoners of the several classes are conducted by different doors. An unfinished house in the town was converted to a theatre, where some comedians occasionally repair from England to perform during a few months of the year, and there are regular assemblies in winter. A public library was established by the Rev. Mr Falle in the 17th century, which since that time has received considerable accessions. There are three gazettes in French published here on Wednesday, and one in English on Saturday. A weekly market is held for fish and provisions, which is well supplied, especially from the coast of France since the late peace; most of the flour is brought from that country and England. Several packets are established between St. Helier's and Weymouth, and there are regular traders to Southampton, whither the voyage is usually made in between 16 and 24 hours. The town of St. Aubin's stands on the opposite side of the bay, to which it gives name, about four miles from St Helier's. It is a small place, situated under a long range of cliffs, and consists principally of one street, well sheltered from the prevalent winds, and commanding a fine and interesting prospect of the bay. Being distant from the church of St Brelade, to which parish it belongs, a neat chapel has been erected by private subscription. This town is protected by a fort mounting 14 guns, which has been erected on a rock dry at low water, but insulated with the rise of the tide. A strong pier projects from the fort, within which there are 30 feet water at new and full moon, and although this is merely a tide harbour, St Aubin's, on account of it, enjoys some portion of foreign trade.

Fortifications.

Jersey, from its peculiar situation, has been strengthened by more than an ordinary portion of military architecture. Elizabeth Castle, which is the proper residence of the governor, is a strong fortress in St Aubin's Bay, defending the approach to St Helier's, from which it is distant 663 geometrical paces, and is accessible by a sandy beach during five or six hours while the tide ebbs, but is insulated with its flow. A fortification, which was recently constructing on the town hill overhanging St Helier's, is designed to contain 2000 or 3000 men. Here a well has been sunk 233 feet through the solid rock, which has from 80 to 100 feet of fine water. Besides these, may be named other strong places, as Mont Orgueil, Fort Henry, La Rocco, Seymour Tower, a fort at Noirmont Point, and Ich-Ho; as also a chain of Martello towers, redoubts, and batteries in every maritime part of the island. Barracks for the accommodation of regulars are erected in various quarters. In the time of war there were, belonging to the island, a troop of cavalry, six battalions of militia, consisting of above 2000 men, and a company of artillery amounting to 600 or 700.

Manufactures, commerce.

Few manufactures are conducted on a large scale in Jersey. About 24,000 hogsheads of cider, however, which is the common beverage of the island, are made annually; and a plentiful year will yield 36,000. Tanning, soapmaking, candlemaking, and other works, are among the manufactures for supplying the inhabitants. Great quantities of worsted stockings are spun and knit in the island. The principal exports are cider, of which 1800 hogsheads are sent to England; fruit, potatoes, cattle, and worsted stockings. During the five years preceding 1813, the exports were at an average 768 cows, 13 bulls, 900 pipes of cider, 1228 tons of potatoes. From England are imported corn, flour, seeds, live and dead stock, cloth, linen, crockery and glass ware, paving stone, and in general all articles necessary for subsistence, apparel, and furniture. Salt fish to a large extent is imported from Newfoundland. The commercial relations of Jersey were formerly restricted for the most part to England and France, after which another field was opened to that island, where about 80 fishing vessels

Exports and imports.

were employed during peace; and now it trades with almost every country in Europe, and also with America. During the year 1813, there entered inwards 734 vessels, and 813 cleared outwards, of which 440 were in ballast. Those constituting the difference, 79, were vessels from England for oysters, which make no entry inwards, but clear outwards. Fifty-nine vessels, whose united burden amounted to 6003 tons, and navigated by 549 men, belonged to the island in the year 1812. Until lately, the currency of the island was principally French, with a small proportion of Spanish money; and the amount of specie was about £80,000 Sterling. After the French Revolution, the coin of England came into more gradual use, until, by the gradual rise of gold and silver, almost the whole specie of the island was withdrawn. The established banking-houses, of which there were three, became obliged to issue notes of five and ten shillings value. Others soon adopted the same plan; and at length no fewer than 80 bankers were circulating notes, from the value of one pound down to one shilling. From the want of coinage of low denomination, they were readily taken; but the hazard inseparable from such an inundation of paper money was diminished by the introduction of £10,000 of silver coinage by government, accompanied by a prohibition against issuing notes of lower value than one pound. Mr Colquhoun, in his work on the *Wealth and Resources of Great Britain*, computes, that the total worth of the island, as property, is £2,610,030. In this estimate are included the value of the soil, of the public and private buildings, farm stocking, shipping, furniture, and coinage; but probably the whole is not worth above £2,000,000 at the highest calculation.

Government.

Jersey is under a peculiar form of government, which some have supposed to be exactly similar to that of the British islands. It consists of a court of judicature, and an ecclesiastical body separately exercising their respective jurisdiction, but which, together with twelve constables, and a military governor, are combined into an *Assembly of the States*. The court of judicature is composed of a bailiff, who presides, and twelve jurats; together with an attorney and solicitor-general, a high sheriff, two under sheriffs, six pleaders, and an usher. The bailiff is appointed by the king, and the jurats are chosen by the masters of families: he keeps the public seal, which however he cannot use without the consent of three jurats. The clergy consist of eleven rectors and a dean, corresponding to the twelve parishes in the island, and forming a regular spiritual court, of which the dean is the head. In the assembly of the States, the attorney-general and high sheriff are admitted *ex officio*, but have no vote. No assembly can be held without the governor's permission, who has a negative voice. But by an order of James VI. in council, he must summon the States within 15 days if the bailiffs or jurats require it. Likewise he is directed to abstain from using his negative voice, except in such points as shall concern the king's special interest. Seven of each class of jurats, clergy, and constables, must be present to constitute an assembly of the states, whose business is chiefly raising money for the public service. There are several peculiarities in the laws of Jersey, of which a code was compiled by the States in 1771, and sanctioned by the king. Legitimation by subsequent marriage is recognised, and the *cessio bonorum* of the Scottish law. The punishment of death is seldom inflicted; but mutilations are practised: A criminal convicted of forgery, which is not a capital crime, was sentenced in 1814 to lose the tip of his right ear.

Antiquities.

Falle, the historian of Jersey, observes, that there are "yet remaining in this island, some old monuments of paganism. We call them *poquelays:* they are great flat stones, of vast bigness and weight, some oval, some quadrangular, raised three or four feet from the ground, and supported by others of a less size. At ten or twelve feet distant is a smaller stone set up on end, in manner of a desk, where it is supposed the priest kneeled and performed some ceremonies while the sacrifice was burning on the altar." The monuments here alluded to are cromlechs, which the author, from the quantity of ashes found around them, and their position on eminences near the sea, supposes were altars dedicated to its divinities. Only four of a decided character now remain, one of which is broken down. Jersey had formerly an abbey, dedicated to St. Helier, four priories, above twenty chapels, and twelve parish churches. All the last, which were consecrated between 1111 and 1341, are still preserved, and some of the chapels.

History.

Jersey is supposed to be the island mentioned under the name of Cæsarea, in the itinerary of Antoninus, and to have thence derived its present name. It is said to have been afterwards called Angia, in a grant by Childebert king of France in the sixth century. About the year 857, it is affirmed that a certain St. Helier suffered martyrdom here, but how, or for what cause, or wherein his sanctity consisted, we are not informed. Indeed these early notices are extremely obscure and indefinite. Having belonged to Normandy of old, Jersey became an appendage of the British isles, when William the Conqueror subdued England; and it was annexed to the crown, along with those in the neighbourhood, by Henry I. However, the French made frequent endeavours to recover what they conceived pertained more naturally to their kingdom, from geographical position, and in the course of the civil wars between the houses of York and Lancaster, they reduced about one half of the island. In the year 1518, it was visited by the plague, which became so destructive in the town of St Helier, as to occasion the removal of the courts of justice and the market. About this time the superficies was partitioned among a number of petty owners, whose oppressions and dissensions were such, that Henry VII. instead of himself applying the sword of justice, which might have produced extermination, obtained a papal bull, excommunicating those guilty of intestine commotions. In the reign of Queen Mary, the island was surprised by a company of Flemings, who probably did not retain it long; and it participated deeply in the civil wars of Charles I. and his son. From that period Jersey seems to have enjoyed profound repose until 1779, when an unsuccessful attempt to take it was made by a body of French troops. In January 1781, the Baron De Rullecourt endeavoured to capture it by a coup-de-main, with 1200 men But part of his force being wrecked, only 700 gained the shore, who surprised the town of St Helier, took the lieutenant governor prisoner, and compelled him to sign articles of capitulation, and likewise to direct the troops and fortresses to surrender. But the officers who held the fortresses, having learned that these orders were given by the lieutenant governor while under restraint, refused obedience; and a body of military, having collected under Major Pierson, speedily expelled the enemy, though with the loss of their own brave commander. Distant 17 miles from Carteret and Bail on the coast of Normandy; 21 from Guernsey; 75 from Weymouth; and 120 from Southampton. Lat. of St. Aubin 49° 12′ 59″ N. Long. 2° 10′ 44″ W. (c)

Jersey, New.

JERSEY, NEW, one of the United States of North America, is situated between 39° and 41° of North Lat. and 74° and 75° 29′ of West Long. Its length from north to south is 160 miles. Its least breadth in the centre 42 miles. Its greatest breadth in the north 70 miles, and in the south 75. It contains nearly 8320 square miles, and 5,324,000 acres. It is bounded on the north by New York, on the east and south-east by Hudson's River, New York Bay, and the Atlantic Ocean; and by Delaware Bay and River on the south-west and west, by which it is separated from the states of Delaware and Pennsylvania. The state is divided into 13 counties, which contain 116 towns, viz.

No. of Counties.	No. of Towns.	Population.		Chief Towns.
	.	1800.	1810.	
Cape Mary	3	3,066	3,632	Bridgetown.

Morris . . .	10	17,750	21,828	Modesttown
Total . . 13	116	211,149	245,562	

General aspect.

The three northern counties of this state are mountainous, and the next four are agreeably diversified with hills and vallies. The south mountain, which is one great ridge of the Alleghany range, crosses the state in Lat. 41°, and the Kittatinny ridge passes a little to the north of the south mountain. The highlands of Navesink, on the coast, near Sandyhook, are about 600 feet above the sea. The greater part of the six southern counties are occupied with that long range of flat land, which commences at Sandyhook, and lines the coast of the middle and southern states.

Soil and agriculture.

Nearly four-fifths of the six southern counties, or two-fifths of the whole state, are entirely barren, producing only shrub oaks, and yellow pines; but the rest of the state contains good soil, and excellent pasturage. Great numbers of cattle are raised in the mountainous parts for the markets of New York and Philadelphia, and wheat, rye, maize, buckwheat, potatoes, oats and barley, are raised for home consumption. Large dairies are also kept, and great quantities of butter and cheese made.

Manufactures.

Great quantities of leather are manufactured at the valuable tanneries of Trenton, Newark, and Elizabeth-town. There is a considerable shoe manufactory at Newark, a glass house in Gloucester county, and paper mills and nail manufactories are erected and wrought to advantage in several parts of the state. The iron works, which are a great source of wealth, are erected in Gloucester, Burlington, Sussex, Morris, and other counties. There are no fewer than seven rich iron mines in Morris county, two furnaces, two rolling and slitting mills, and about 30 forges, with from two to four fires each. The annual produce of these works is about 540 tons of bar iron, 800 tons of pigs, besides large quantities of hollow ware, sheet iron, and nail rods. In the whole state, the annual produce is computed at 1200 tons of bar iron, 1200 tons of pigs, and 80 tons of nails, exclusive of small articles.

Commerce.

The annual amount of articles exported from the seaports of New Jersey, was, in 1810, 430,267 dollars. The aggregate tonnage of the state for 1807, was 22,958. The exports through New York and Philadelphia are very great. The exports are flour, wheat, horses, cattle, hams, cider, lumber, flax seed, leather, and iron.

Rivers.

The principal rivers in New Jersey, are the Delaware and Hudson rivers; the Passaic, which is navigable for 10 miles, and has very interesting cataracts at Patterson; the Hackinsac, which is navigable 15 miles; the Great Egg Harbour river, which is navigable 20 miles for boats of 200 tons burthen; the Maurice, which is navigable for 20 miles by sloops of 100 tons; and the Musconecunk, which runs into the Delaware.

Towns.

The principal towns of the state are *Newark*, a flourishing well built town, with a population of 8008 in 1810; *Trenton*, the seat of government, with a population of 3002; *Perth Amboy*, so called from James Drummond, Earl of Perth and Ambo, with a population of 815; *Burlington*, with a population of 2419; *New Brunswick*, where there is a college, founded in 1770, and a population of 6312; *Princetown*, a village with 80 houses, where there is a celebrated college called Nassau Hall, founded in 1738; and *Elizabeth Town*, with a population of 2977.

Literature.

Besides 15 incorporated academies, this state has two colleges, viz. the college at Princetown, and Queen's College at New Brunswick. The college edifice at Princetown is of stone, and is 180 feet in length, 54 in breadth, and 4 stories high, and divided into 42 convenient chambers for the accommodation of the students, besides a chapel, dining hall, and room for the library. A theological seminary with two professors, has lately been added to this establishment. In winter, there are from 70 to 80 students in the five classes of the college, exclusive of the grammar school; and in the summer from 80 to 90. The college at New Brunswick was founded by ministers of the Dutch church for the education of their clergy, and was incorporated in 1770.

Religious state.

There are a number of different religious denominations in New Jersey. The Presbyterians, who are the most numerous, had, in 1811, 64 churches, and 42 clergymen; the Dutch reformed churches 64, and 42 clergymen; the Episcopal church 24 churches, and 10 clergymen; the Baptist church 30 churches, and 23 clergymen; the Congregational churches 9 churches, and 5 clergymen. The Methodists are very numerous; the number of their communicants was about 6739 in 1811. The Quakers have 44 meeting houses in the state.

History.

This state was included, in 1664, in the patent of Charles II. to his brother the Duke of York and Albany, who soon after conveyed it to Berkely and Carteret. In the same year, three inhabitants of Long Island purchased from the Indians a tract of land, and called it Elizabeth Town; and in the year following, the colony received its own governor Sir G. Carteret, and became a distinct province.

Inhabitants.

The inhabitants are a collection of Low Dutch, Germans, English, Scotch, Irish, and New Englanders, or their descendants.

Population.

In 1810, the population was,

Males	115,357
Females	111,511

Total population in 1810, 226,868

The militia in 1810, amounted to 33,710 men. See Morse's *American Geography*.

JERUSALEM, a city of Palestine, in the pachalic of Damascus, and the capital of the ancient kingdom of the Jews. It occupies the declivity of a barren basaltic mountain, at the extremity of an extensive plain, in a climate comparatively cold, from its elevated situation, where much snow falls, together with copious rains. The plan of the city is irregular; but excluding the citadel at the west end, it approaches to a quadrangular form. It is surrounded by crenelated walls of reddish freestone of considerable height, strengthened by square towers, and mounting a few old 24-pounders, on carriages without wheels. The walls are modern, having been built by Soliman, the son of Selim, as appears from inscriptions upon them. They are too thin to admit of defence, and Jerusalem is not tenable as a military post, being commanded by neighbouring heights on all sides. There are six gates, whose names are partly of Hebrew origin. The total circuit of the city does not exceed two miles and a half. Some authors exaggerate its ancient limits to a great extent, while others conclude that it has scarcely ever exceeded its present boundaries. The streets are narrow, as is usual in the east, but straight and well paved. Several of them have foot-paths, and they are kept cleaner than is common in Palestine. Vacant spaces, and some covered by ruins, are seen towards the west, but no open square has been purposely left within the walls. In general, the houses are well built of free-stone, and for the most part two or three stories high, with a plain simple front, without windows in the lower stories, so that it has been said that a passenger walking the streets of Jerusalem may conceive himself in the corridor of a vast prison: the door, besides, is so low, that a person must bend almost double to gain admission. The roofs are either terraced, or rise in domes, and the dull uniformity of the whole is interrupted by the steeples of the mosques and churches, and the tops of a few cypress trees, and tufts of nopals. Some houses have small gardens.

Inhabitants.

The total population of Jerusalem amounts to 30,000; but from having been peopled by Jews originally, this city exhibits a great mixture of other nations, whose appearance, habits, and sentiments, are at considerable variance. Of these it is computed that 20,000 are Christians of different sects and denominations; 7000 Mahometans, Turks, or Arabs; and only a few Jews. About 2000 of the Mahometans are fit to carry arms. The men are distinguished by no peculiar character. Handsome women are rarely seen: they are in general of a melancholy disposition; of a pale deadly white complexion, and ungraceful mien. The circumstance of wearing a white veil or a fillet round their faces, makes them resemble so many walking corpses; but the faces of the Christian females are exposed as in Europe. Much variety of costume is beheld in the streets; every one, whether Jew, Arab, Syrian, or Turk, adopting what he prefers. The lower orders, however, usually wear a shirt of white or black, or one of broad striped brown, as in Arabia. Christians and Jews wear a blue turban as a mark of distinction, though a few diversify the colour; and shepherds in the neighbourhood have theirs white or striped like the Mahometans. It ought not to escape observation, that blue is in many parts of the East a characteristic of Christianity; and it is not unlikely that its frequency among the lower classes in some parts of Europe has a similar origin. Persons in easy circumstances adopt the Turkish costume, with a high turban. Both the Turkish and Arabic languages are common in Jerusalem.

The mode of life among the inhabitants is dull and monotonous. They have little to interest them: no active pursuit of manufactures, arts, or sciences; no general bond of union; no object of common interest in view. They labour under the oppression of a despotic government, which exercises incessant extortions, without encouraging the means which would enable the people to satisfy its avarice; and so obnoxious is the pasha, that on his approach the inhabitants desert the city. Almost all the Christians entertain a decided antipathy to each other, independent of which a strong aversion subsists between them and the Mahometans. All the different sects reciprocally consider the rest as schismatics and infidels. Those of each persuasion believing that they alone possess the true light of heaven, and an exclusive right to enter paradise, consign the rest without distinction to the infernal regions. Nevertheless, this apparently goes no farther than words; for there is more unrestrained intercourse among the inhabitants of Jerusalem, than of any other place under the sway of Mahometans, which is supposed to arise from the predominant number of Christians. Some sociality is practised among them; and even Christians and Mahometans mix indiscriminately together. All the former, of whatever sect or denomination, devoutly implore the downfal of the Turks; and certainly with sufficient reason, for one leading feature in the political economy of Mahometans is extortion from those who are incapable of resistance.

The sciences have entirely disappeared from Jerusalem. Formerly, there existed large schools belonging to a Mussulman temple, but at present hardly any traces of them remain, and only a few subsist where children of every sect learn to read and write the tenets of their respective religion. The grossest ignorance is found to prevail among persons of the highest rank, who, on the first interview, seem to have received a liberal education. The arts are nearly in a state of equal degradation: a late traveller affirms that he did not see a single lock or key of iron during his abode in the city. There are some weaving looms, and very handsome yellow slippers are made, but the other manufactures are apparently inconsiderable. An immense quantity of relics was wont to be made for the convents, as it is not evident that these were fabricated within their walls; which was either for export to Catholic countries, or to supply those whose devotion led them hither in pilgrimages. The traffic is not yet abandoned. Jerusalem forms a kind of central point between Arabia, Egypt, and Syria, and is a rendezvous for the Arabs of these three countries, who come for the purpose of commercial concerns. But the chief trade of all Palestine consists in exporting oil and importing rice by the way of Acre. However, little benefit seems to be derived from it by Jerusalem. Possibly those who have contemplated its former grandeur in history draw a contrast with its present state, which is scarcely warranted by the reality; for the activity required by the very supplies which a city of 30,000 inhabitants demands, is inconsistent with the picture of desolation which some travellers, such as Chateaubriand, give of the streets. "Enter the city; nothing will console you for its sad exterior: you wander over an unequal surface in narrow unpaved streets, walking amidst clouds of dust, or among rolling flints. The darkness of this labyrinth is heightened by cloths stretched between the houses. Vaulted bazars, replete with infection, deprive the desolate city of the remaining light. Some mean shops display nothing but misery to the sight; and they are frequently shut up from the dread of a cadi passing near them. No one appears in the streets —no one stands at the gates of the city. Sometimes only a peasant glides along in the shade concealing the fruit of his labour under his vestments, in the apprehension that a soldier may despoil him of it. All the noise which is heard in the city is the galloping of a horse in the desert bearing a janisary out on his way to pillage, or carrying him home with the head of a Bedouin Arab." Jerusalem is abundantly supplied with game: provisions of all kinds are cheap, and the wine is good. The shops and markets are, in the ordinary streets, not restricted to a separate bazar, as is usual elsewhere.

Pilgrims. Independent of the stationary inhabitants and the other subjects of the Turkish government, Jerusalem is a great resort of pilgrims, among whom were many Europeans in former times. But though the zeal for pilgrimage has greatly declined, yet it is still very considerable. In 1806, the number amounted to 1500, which was thought small; but there were only two Europeans, of whom one was a traveller. It has been believed that the visits of Catholic pilgrims were the source of great riches to the convents of Jerusalem—a point disputed by Chateaubriand, who quotes various instances to confute the assertion. The city swarms with mendicants, allured thither in expectation of alms from the pilgrims.

Public officers. Jerusalem has a governor, who lives in state, and receives strangers in a dignified manner; a cadi, or civil judge, who is sent annually from Constantinople; a governor of the citadel; a sheik el haram, or chief of the Mahometan temple; and a mufti, or chief of the law.

Edifices. This city is particularly interesting to Europeans, in having been the capital of a people from whom all their religious opinions are derived, and from being the theatre of some events, which not only excited great sensation at the time, but have been carefully transmitted to posterity. Its public edifices are still numerous: the spots which are mentioned in Scripture in the environs are yet pointed out with pious anxiety; but it must not be disguised, that some recent travellers, leaning more to ancient history than the affirmation of the moderns, begin to question the identity of the localities which have remained undisputed for ages. **Citadel.** The present citadel, which is supposed to occupy the site of David's palace, is a Gothic edifice throughout, with interior courts, fosses, and covered ways. No cannon are seen on its walls; and in one deserted apartment, full of old helmets, lie numbers of weapons resembling musket barrels, of which the use is now unknown. This structure is also called the Pisan's Tower, having been built, according to Doubdan, by the republic of Pisa, when the Christians were in possession of the Holy Land. But the religious edifices are more important and interesting. **Convents.** There are several convents of Christian monks, whose total number in 1807 amounted to 61; and of these no less than 48 were natives of Spain. The Franciscan convent of St Salvador is a spacious structure like a fortress, which, with all its conveniences in relation to the usual accommodations of Palestine, has been compared to "a sumptuous and well furnished hotel, open to all comers who may be attracted hither by curiosity or devotion. Meals are served up in an apartment called the Pilgrim's Chamber, consisting of sufficient variety, and adapted to every national taste. Even the beverage of tea is copiously supplied to the Dutch and English, and abundance of liqueurs may be obtained." All pilgrims are received here: on their arrival, they undergo some ceremonies, and the feet of Europeans are washed by the superior of the convent. They are lodged and supplied with whatever they require, and conducted to every sanctified place; but the duration of their residence is limited to a month. It is common for persons of condition to make a present to the convent on their departure, which, in Pococke's time, amounted to about £6 sterling. At present, however, their table is apart from that of the fathers: they bear their own expences, and the convent derives no advantage from their residence. Only the poor are gratuitously maintained. The funds of the convent are ample, being the result of donations from Catholics of all ranks, and especially Catholic princes, either in money or in goods and merchandise. But the monks were lately reduced to great distress from the interruption of their European supplies by the war; and they are also occasionally harassed by the exactions of the Turkish officers. In eight years of the present century, they were compelled to pay 40,000 piastres, or about £6000. Nevertheless, they have obtained the esteem of the people among whom they dwell, by their excellent organization and the regularity of their conduct. The Armenian convent is the largest in Jerusalem. It is maintained in a degree of splendour, attended with neatness, cleanliness, and good order unexampled in Palestine. "Every thing pertaining to it is oriental. The patriarch appears in a flowing vest of silk instead of a monkish habit, and all around him bears the character of eastern magnificence. He receives his visitors in regal stateliness, sitting amidst clouds of incense, and regaling them with all the luxuries of a Persian court."

Sepulchre of Christ. The church of the Holy Sepulchre has been celebrated for ages as containing within its precincts a tomb believed to be that in which the body of Jesus Christ was deposited. This structure stood on Mount Calvary. It consisted of several churches united; and, besides the tomb, covered about twelve places consecrated as the scenes of remarkable transactions. The tomb itself, a white marble sarcophagus of ordinary dimensions, occupies a subterraneous chamber highly decorated. Its sanctity, however, is denied by Mahometans; and the later travellers, though they rest their opinions on very different principles, have called its identity in question. The former deny its sanctity, because Christ ascended to heaven after imparting his likeness to Judas, who was crucified in his stead; and the latter doubt its identity, because there is no evidence that the tomb attracted any notice until centuries subsequent to the event. Nay, they are disposed to go much farther, and to question the identity of all the localities pointed out as those of scripture, partly because the topography of the moderns is inconsistent with ancient descriptions, and partly from the cause above assigned, that such points were not determined until the age of the Empress Helena, who lived some centuries after the death of Christ. Under this impression, the real sepulchre has been sought for among the neighbouring catacombs of a hill facing Mount Sion. The empress now named is said to have founded the church of the Holy Sepulchre from the real cross on which Christ suffered being discovered on the spot; and the tomb was covered by a superb rotunda forming one end of that structure, which has been lately destroyed by fire. This conflagration is ascribed to the Armenians, who sought, by these means, to gain possession of the whole edifice, which was partitioned into churches and chapels belonging to various sects professing the Christian religion. The monks who superintended the sepulchre were particularly the objects of Turkish oppression, which the sincerity of their devotion alone could enable them to support. They not only suffered grievous exactions, but were repeatedly exposed to personal insult and danger. The Mussulmen of Jerusalem themselves revere the tombs of many saints, which afford a profitable speculation to individuals, either from the pious endowments annexed to them, or the collection of alms.

Jewish synagogue.

At present the Jewish synagogue is a miserable structure, consisting of three or four apartments, with roofs so low that they may be reached by the hand; the whole is covered with filth and cobwebs, and disgustingly dirty. The Jews of Jerusalem are restricted to a certain quarter, and are represented as living in a very miserable condition.

Mahometan temple.

This city is equally sanctified in the eyes of Mahometans as of Christians. They call it *el Kods*, or the holy, and have a magnificent temple here, whose interior has been anxiously veiled from the latter. Their presence would be deemed profanation; and although Dr Clarke was furnished with the most powerful of all recommendations, the governor of Jerusalem declared, that the forfeiture of his own life would follow his consent to give him access. But we are now in possession of a detailed description of it from an enterprising traveller, who more recently traversed much of the east under the guise of a Mahometan.

The disciples of the prophet acknowledge two sanctified temples, that of Mecca, and that of Jerusalem; both are named *el Haram* by way of distinction, and are alike prohibited to Jews, Christians, and all who do not profess the Mussulman faith. Mosques are merely named the place of assembly; and although the entrance of infidels is not specially prohibited, it is unwelcome, and must be sanctioned by an order of some public authority. "But no Mussulman governor dares to allow an infidel to pass into the territory of Mecca, or into the temple of Jerusalem. Such a permission would be deemed a horrid sacrilege; it would not be respected by the people, and the infidel would become the victim of his own temerity." Solomon's temple, which has so often been held up to admiration, while many superior works have passed unnoticed, was totally destroyed when the city was sacked by the Romans. An Arabian historian relates, that, on being taken by the Caliph Omar, he enquired, what would be the most suitable place for erecting a mosque, of the patriarch Sophronius, who led him to the ruins of the temple. A new edifice was raised upon their site, which consists of a court, or enclosed square, 1369 feet long by 825 broad. The whole has not been constructed at once, however, as it is a group of mosques erected at different times. Access is gained by nine gates, entering on the north and west sides. The principal part of the structure is composed of two piles of magnificent buildings, called *el Aksa* and *el Sahara*, which, in their respective situation, may be considered as two distinct temples, but together form one consistent and symmetrical whole. *El Aksa* is composed of seven naves supported by columns, and the centre nave is surmounted by a fine spherical cupola, with two rows of windows, and richly ornamented with arabesque paintings and gildings of exquisite beauty. This cupola is 32 feet in diameter, and is sustained by four arches, reposing on four square pillars, the different sides of which are enlarged with handsome columns of brown marble. Each side of the nave which it crowns rests on seven arches slightly pointed, springing from cylindrical pillars above two feet and a half in diameter, and sixteen high. The walls rise thirteen feet above the tops of the arches, and each contains two rows of windows. A frontispiece, inlaid with pieces of beautiful marble, ornaments the niche from whence the Imam directs the prayer, with six small columns of white and green decorating the entrance. In a vault at one side the Caliph Omar was accustomed to pray. A causeway, 284 feet long, fronts the principal gate of the temple, in the middle of which is a fine marble bason, with a fountain in form of a shell that formerly supplied the water; and at the end of the causeway is a fine staircase leading to the other temple *Sahara*, which takes its name from a rock greatly revered in the centre of the edifice. This temple is octagonal, 61 feet of a side, and 159 in diameter. It occupies a platform 460 feet long, 399 broad, raised 16 feet from the ground, which is ascended by eight staircases. The exterior is encrusted to half its height with various kinds of marble, and the remainder covered with small bricks, or squares of different colours. On each side of the octagon are five large windows filled with glass finely painted in arabesques. The temple is entered by four gates, on the north, east, west, and south, and is surmounted by a cupola also, elevated 93 feet above the surface below, which is a superb spherical segment, with two rows of large windows, and is supported by four large pillars, together with 12 magnificent columns ranged in a circle. The rock of Sahara approaches the segment of a sphere 33 feet in diameter; it is of its natural shape; the surface rugged and uneven. Here the Mahometans exhibit the print of their prophet's foot when he came to pray; and they believe, that, next to the temple of Mecca, the prayers of mankind offered up at the rock of Sahara are the most acceptable to heaven. It is surrounded by a high gilt railing, and the sacred impression itself is protected by a cage of gilt wire. The Mahometans are taught that it is surrounded by an ordinary guard of 70,000 angels, which is daily relieved, and that other invisible troops of angels and prophets resort hither to offer up their prayers. In the pavement near the rock is a piece of waved green marble or jasper, fastened down by four or five gilt nails, which, however uninviting, they affirm is the gate to paradise. Some of the nails they relate to have been removed by the devil attempting to pass, but he was overheard in time, and beaten back for ever. In this temple there is preserved a koran of enormous size, being four feet long, and above two and a half broad, which was used by the Caliph Omar. Every night 180 lamps are lighted up here, and 175 in the mosque Aksa. Besides these two structures, there are several others, and also platforms for oratories, within the spacious limits of the Mahometan temple, on one of which the throne of Solomon is supposed to have stood.

Hospital.

Not far from the centre of the city is a magnificent building called the hospital of St Helena, which is still devoted to charitable purposes. Every Mahometan presenting himself at the gate formerly received a supply of food, but the extent of the charity has declined.

Environs of Jerusalem.

It must not be conceived, that the few edifices hitherto named exhaust the curious and venerable remains of the capital of the Jews. On the contrary, they are so numerous, that authors divide them into six different classes: 1. Those purely Jewish; 2. Greek and Roman monuments in the time of the Pagans; 3. Greek and Roman monuments under Christianity; 4. Arabian or Morisco monuments; 5. Gothic monuments under the kings of France; 6. Turkish monuments. Many places without the walls of the city are alike interesting, as the brook Kedron, the pool of Siloe, the valley of Jehosaphat, and the mount of Olives. On this last, which is called Djebel Tor by Mahometans, the Christians assert 7200 prophets have been buried; and here also is a Christian church, containing a marble slab with an impression of the foot of Christ left as he ascended to heaven. The city occupies a portion of mount Sion. In the neighbourhood there are numerous ancient catacombs excavated in the sides of the hills, where brief Greek inscriptions are seen on some of the tombs, and ancient paintings on the walls, executed after the manner of those discovered in the subterraneous cities of Herculaneum and Pompeii.

History. According to the Jewish chronology, Jerusalem was founded by their high priest Melchisedeck in the year of the world 2032, and was originally named *Salem*, which signifies peace. But its principal glory was reserved for Solomon, a wise and politic prince, who lived a thousand years later, and founded the celebrated temple, whose riches are the admiration of posterity. The history of the temple is thenceforward in a great measure to be considered as the history of Jerusalem. It was destroyed 600 years anterior to the Christian era, but afterwards rebuilt; and Alexander the Great is said to have offered a sacrifice in it to the deity worshipped by the Jews. Jerusalem frequently became an object of contention among surrounding nations, and suffered all the vicissitudes common to eastern cities. It was repeatedly pillaged; its inhabitants slain or led into captivity: and the conquerors erected statues of their own divinities in the temple. At length Judæa became a Roman province, and our Saviour was soon after put to death by order of the governor, for declaring that he was king of the Jews. Probably the governor thought the punishment too severe; but being viewed as a political offence, he found it expedient to yield to the voice of the people. Judæa being treated as a conquered country, the inhabitants revolted; which led to the celebrated siege of Jerusalem by Titus, in the year 71. All the sufferings induced by famine were endured; the vilest substances were welcome food; and parents even devoured their own children. The city was stormed, after a brave and vigorous defence; and the miserable citizens inhumanly tortured to death and butchered by the ferocious Roman soldiery. Not less than 200,000 were computed to have died of hunger, and 1,100,000 perished in the assault. In a new revolt of the Jews, Adrian, in the year 118, completed the destruction of what had been spared by Titus: but a new city called Ælia Capitolina was immediately built, where the presence of the Jews was absolutely prohibited. The name of Jerusalem at length became so utterly obliterated, that during the persecution of Dioclesian, a martyr having said he belonged to it, the governor who heard him supposed it some factious city secretly erected by the Jews. Towards the close of the seventh century, its new name of Ælia Capitolina was still retained. The Christian religion at length found a protector in the Empress Helena, and her son Constantine, who demolished the images of heathen deities, to make way for the erection of crucifixes. An attempt to rebuild the temple by the mild and philosophic Emperor Julian, about 37 years later, is recorded to have proved abortive, from fiery eruptions escaping out of the earth and dispersing the workmen. Jerusalem was taken by Chosroes, King of Persia, in 613, but recaptured by Heraclius in 627. Nine years later, it fell into the power of the Caliph Omar, the third in succession from Mahomet, after a siege of four months; and having undergone still farther revolutions, suddenly became an object of ambition among European potentates, who, notwithstanding their reciprocal contentions, united in disturbing the peaceful possessors of Palestine. During the crusades of 1099, they conquered Jerusalem, and established a sovereignty in Syria, which continued with some interruption until the year 1291, when they were totally expelled. Selim, emperor of the Turks, early in the sixteenth century, finally annexed all Syria to the Ottoman empire, under which it still remains. (*c*)

JESSO, a large island of Asia, the situation, extent, and description of which, have presented the most embarrassing problems to modern geographers. Some have supposed it to be a continent little inferior to Europe in dimensions; others reduce it to an inconsiderable island; and it has also been conceived to be a portion of eastern Asia, very nearly united to the western shores of America. Later observations, however, combined with those of older date forgotten and neglected, have dispelled these obscurities, and satisfactory illustrations can now be given of this particular portion of the globe. **Form and extent.** The figure of Jesso approaches to that of an irregular triangle, extending about 300 miles in length from north to south, and little less in extreme breadth. It stretches from Cape Nadeshda, in 41° 25′ 10″ north latitude, to Cape Romanzoff, in latitude 45° 25′ 50″, the most southern and northern points; and the centre of the island lies in about 217° of east longitude. This island is washed on the west by the Gulf of Tartary; on the east by the North Pacific Ocean; it is divided from Japan by the Straits of Sangar, which are of dangerous and intricate navigation; and separated from the island or peninsula of Saghalin on the north by Perouse's Channel. Its whole circumference is indented by deep bays and inlets, in many places forming secure harbours, by the numerous capes and promontories projecting around them. One of those best known to Europeans is Volcano Bay, towards the south-east, secure and spacious, and containing Endermo harbour, which is completely sheltered by the land. Two lakes are said to be in the centre of the island, each the source of a river flowing into the sea; but none of the estuaries have been surveyed by recent navigators. **General aspect.** The general aspect of Jesso is wild and mountainous: a barren and rugged chain traverses it from north to south, parallel to which it is conjectured that another ranges at some distance. Several of the mountains exhibit active volcanoes, and some of them are extinct volcanoes; three of the former, separated by short intervals, stand on the shore of Volcano Bay. **Productions.** The mineral and vegetable productions are imperfectly described. Gold and silver mines are reported to have been wrought in the eastern parts of the island by the Japanese during the seventeenth century; but they seem to be now abandoned. Neither of these metals, nor precious stones, are valued by the inhabitants. The soil is of unequal quality, and much of the surface is uncultivated. Perhaps also the climate is unfavourable for agriculture.

Productions.

It is remarked, that the northern extremity of Jesso seems to possess many advantages over the southern. Nevertheless about Endermo harbour, the soil is good, and the produce luxuriant. Wild grapes are abundant. The woods contain elm, oak, ash, and all the common trees of England; while the gardens exhibit the ordinary esculent plants. Millet and other grain are plentiful; but the natives are very little addicted to agriculture, as they subsist principally on wild fruits or roots, as the saranna, and by hunting and fishing, although the houses of the Japanese are environed by gardens and plantations. Fish is found in great variety in the surrounding seas. A particular species of anchovies, called nising, of delicious flavour, appears in vast shoals on the surface, driven towards the coast by whales; and quantities of salmon are caught, either for immediate use or winter store. Whales, porpoises, and turtle, are also numerous; but it has been affirmed that the first are unmolested, on account of their services in pursuing the nising. Tripang, or biche de mar, a kind of holothuria prized in eastern repasts, is obtained by diving among the rocks, as also various other animals of the mollusca tribes, whose names are not yet recognised in the works of naturalists; and many crustacea. Of birds, there are numerous aquatic species resembling those of Europe: Eagles are kept tame in cages, and supposed to be an article of food, though it is more probably on account of their feathers for arrows; two kinds of hawk, one of a yellow colour; crows, pigeons, and a yellow bird resembling a linnet. The quadrupeds are horses, which have perhaps been introduced within a century by the Japanese; wolves, foxes, dogs, bears, deer, and rabbits. Deer and bears inhabit the mountains. The latter are seen in considerable numbers among the natives, by whom they are taken young, domesticated, and then killed, and ate as dainties at a certain season, while a portion is used as a medicine. The dogs resemble those of Kamtschatka, but are of a smaller breed. They are trained for draught, and harnessed to sledges in winter, which would indicate, that during a portion of the year the ground is covered with snow. These, however, it is likely, do not exhaust the list of the quadrupeds on this island.

Inhabitants.

Jesso is inhabited by two distinct races of mankind; the aborigines who call themselves Ainos, and the Japanese, who have wrested the island from their possession, and now hold them in subservience. The opinions entertained regarding the former, who also inhabit the island or peninsula of Saghalin, are so singular and discordant as to merit a brief investigation. They have been commonly denominated wild Kuriles, and are supposed to be covered with hair in unnatural profusion—a peculiarity at this day ascribed to the inhabitants of the Kurile Islands. Nor is this opinion more prevalent among the natives of the neighbouring countries than among Europeans who have visited the country. Mozin, a name formerly given to the island by the Japanese, signifies the land of hairy people; and Kannemon, an intelligent interpreter of that nation, by whom it was visited in 1652, says the beards of the men are sometimes two feet long; that the whole face, excepting the eyes and nose, is covered by it; and that the portion depending from the upper lip is raised when they drink. Froes, a Portuguese missionary, who was at Miaco in Japan in 1565, had previously been acquainted with this latter fact, as also that the people were very hairy all over the body; and Saris, an English navigator, learned at Jedo in 1613, that they were as hairy as monkeys. In the fragment which is preserved of the journal of the Castricum in 1643, the hairiness of the whole body, and the size of the beard almost totally covering the face, were both the subjects of observation. It was likewise remarked from her consort the Breskens, a Dutch vessel, which navigated the coasts of Jesso in the same year, that the people leaving the south part in a boat, had long stiff black beards; and in 1738, Captain Spanberg, a Russian, landed on a large island in 43° 50′ north latitude, which if not Jesso itself, as there is some reason to believe, is in its immediate vicinity, where the bodies of the men were wholly covered with long hair. Further, the last English navigator who visited Jesso towards the close of the preceding century, employs these words in describing the natives of the southern extremity. "Their beards were thick and large, covering the greatest part of the face, and inclining to curl. The hair of the head was very bushy, which they cut short before on the forehead, and behind the ears; behind it was cut straight. *Their bodies were almost universally covered with long black hair, and even in some young children we observed the same appearance.*" This combination of testimony would assuredly seem conclusive, did not the still more recent visitors of the Ainos, in the present century, deny that any such characteristic is common among them. Their intercourse, indeed, was more with the northern inhabitants. But in Saghalin they admit that a child of this description was seen, though its parents were distinguished by nothing of the same kind.—We are induced to conclude, upon the whole, that the aborigines of Jesso are more hairy than the generality of mankind. They are somewhat below the middle size, strong and swift, of a dark brown complexion, almost black, with black eyes, and an agreeable physiognomy, and resemble the Kamtschadales, but have more regular features; however, new born children are perfectly white. The women have rather pleasant countenances to the south, while to the north they are ugly, and are scarcely any fairer than the men. The long rough black hair of the latter hangs down from the head behind, and that of the women of the same colour is frequently tied above in a knot, or combed over the face. It is not said that the men lacerate their bodies in any fashion for the purpose of ornament; but the women are tattooed on the hands, face, and feet, and in some parts of the island around the mouth, in flowers or other figures, which are executed by the mother during the earlier age of her offspring. Children go entirely naked. There is little difference between the dress of adults of either sex, but the feet are usually bare. A tobacco box, pipe, and knife, are carried in a belt girding their vestments around the waist. The men wear large ear-rings of gold, silver, or baser metals, according to their rank; the women an ornament of the same kind, consisting of a short chain of two or three silver rings of still greater dimensions. Besides strings of glass beads, and other ornaments, a small shining silver plate or mirror hangs from the neck. Their fashions seem to have undergone little alteration since the earliest visits of Europeans. The Ainos testify a remarkably quiet and placid disposition, intermixed with a large portion of liberality and benevolence. They freely part with their property without any expectations of return, and are always ready to be serviceable. The women are exceedingly timid and reserved, but preserving less gra-

Inhabitants.

vity than the men, who seem tinctured with jealousy, if this may be inferred by their withdrawing them from the view of strangers, and never quitting them for a moment while in their presence. Their oldest visitors describe them as very jealous of strangers when approaching their wives and daughters. Their salutations are exceedingly humble, approaching the strangers who visit their shores in an attitude of abject submission, sitting down cross-legged, stroking their beards, often stretching forth their hands, and bowing almost to the ground.

They speak in a slow and timid accent; and their language, which is peculiar, is intermixed with many Japanese words. They call themselves Ainos, but the real import of this word is not fully understood, whether simply meaning *people*, or distinguishing a particular race.

The Ainos around Endermo harbour, and indeed throughout the island, subsist principally on dried fish, boiled with sea-weed, and mixed with oil. They have also some fruits and vegetables, but excepting about Matzumay, their cultivation of the earth extends no farther than to scanty patches; and subsistence, on the whole, seems precarious. According to the older Eastern authors, all the tame bears are killed in winter, the flesh ate, and the liver reserved as medicinal against poison, and various diseases. But they have little skill in medicine; and in cases of small-pox, or any contagious disorder, they are said to send the sick person to the top of a lofty mountain, or to some remote place. Their houses are built of wood, thatched with reeds, and are generally of an oblong form: The whole family sleep on mats or skins, on a platform around the fireplace, which is in the middle. Small openings to carry off the smoke are made at each end of the roof. Both sexes are very fond of smoking tobacco, yet that plant is not cultivated among them.

The men occupy themselves in the more laborious pursuits of hunting and fishing, while the women are engaged in domestic duties, making cloth of the bark of trees, and sewing and embroidering, which they do very neatly. However, the arts are but in a low state, as is seen in their arms, their boats, and habitations. All articles whose fabrication requires any portion of ingenuity, are supplied by the Japanese. The men are most expert archers, discharging their arrows with remarkable force and precision. The bow is only 37 inches long, the arrow 12 inches; feathered, barbed, and poisoned with so deleterious a substance for killing wild animals, that blood immediately gushes from the mouth and nose, and they die in a few minutes. Their other arms are swords, pikes pointed with iron, and a weapon once known in Europe, which consists of a ball attached by a chain to a handle, somewhat resembling a flail. Their shields are made of seal skin, tripled. They are ignorant of the use of fire arms. The boats of these people are principally built of fir, sewed together with twisted willows, and sharp at both ends. In rowing, each oar or skuller is moved alternately, which prevents the boat from advancing in a straight line.

Manners and customs.

The transient visits of Europeans to Jesso scarcely enable us to speak of the manners and customs of the inhabitants with any degree of certainty, unless in what has casually been the subject of observation; and there is considerable risk of error in misinterpreting what the natives of Japan have written regarding them. Polygamy is said to be practised here without any regard to consanguinity: a brother marries his sister, and the men have from four to eight wives, according to their circumstances. Adultery is punished by cutting the hair off the offender. The infringement of ordinary contracts is attended with the forfeiture of something exceeding the value of the engagement. A tree is planted on the graves of their dead, and blood is then spilled either by mutual encounters somewhat similar to the practice of the savages of New Holland, or by voluntary lacerations, as are frequent in other parts of the world. No external demonstrations of religion have been observed among the Ainos, in temples or places of public worship; neither does it appear that they adore supreme or intermediate deities, though before eating and drinking they offer up a prayer, and likewise pray during sickness.

Political state.

In regard to the political state of this island, the Japanese seem to be masters of the whole, and to employ the natives exclusively for their own benefit. It is divided into five districts, and the government is committed to the prince of Matzumay, but whether he is resident here, or on a neighbouring island, or in Japan, is not explained. We should rather infer that the executive is committed to a viceroy, who lives in the town of Matzumay. It is certain that the Ainos are tributary to the Japanese, and among themselves they have no form of government. Each district is under a chief, whose consideration is proportioned to its extent and population. The inhabitants always add the name of their district to their own name; another peculiarity coinciding with the practice of the New Hollanders. Probably they are collected chiefly towards the coast, where a number of their villages appear; but it is not likely that the island is populous.

It is difficult to form any precise opinion regarding the degree of civilization which has been attained by the Ainos. They are considerably removed from the state of savages, not only in the absence of ferocity, a general attribute, but both in food and clothing. Yet they seem to have undergone only the slightest changes since they are first mentioned in history. A Japanese author of 1720 compares the condition of the Ainos to that of his countrymen 660 years before Christ: "They are ignorant of all ceremonies and social ties, and differ but little from brutes: they eat raw flesh, and drink the blood of animals, nor are they aware that viands cooked are more savoury than raw. Nevertheless, at different places on the east coast they have for some time learned the cultivation of the earth, and to sow grain, from the Japanese; but they are unacquainted with the two seasons for planting rice."

Matzumay.

Besides the aborigines, it rather appears that there is a different race dispersed in scanty numbers in the island, of which no correct intelligence is yet obtained. But the Japanese have been long settled here in different establishments on the coast, the principal of which is Matzumay, said to signify the town of firs. It is situated towards the south-west extremity of the island in Lat. 41° 32′ north, and Long. 219° 56′ east, extending along the margin of an open bay about four miles wide at the entrance, and ascending the rising grounds behind, interspersed with trees and gardens. This town, which has not been visited by modern Europeans, is of considerable magnitude, built of wood and fortified. There are a light-house or observatory on the west side of the bay, which is much frequented by shipping, and two small islands opposite to the town. Between Matzumay and Japan constant and regular intercourse is carried on, but it would seem that the Ainos have always had some channel of communication with Corea or

Jesso.

Tartary. They pay a tribute to the prince of Matzumay, which for those on the coast consists of fish, and for those in the interior of game: and this prince acknowledges the supremacy of Japan by presents and other acknowledgments to the sovereign.

During the greater independence of the Ainos, they resorted to the northern parts of Japan for the purposes of traffic with peltry and the skin of a kind of seal called rakko, a certain marine plant, eagles feathers for arrows, and other commodities; and at present, though subservient to that nation, it is probable some trade is carried on with them.

History.

To trace the history of an island which has been enveloped in so much obscurity, doubt, and perplexity, would be no easy matter. In the words of a learned geographer, who wrote in the middle of the preceding century, "no country of the terrestrial globe has been so differently represented for these last 150 years as the land of Jeso, Jezo, Yeço, Eso, Jedso, Jesso, Yesso," names by which, as well as Insu, it was known. The Japanese seem to carry back the history of this island to a period corresponding with the second year of the Christian æra, at which time it was probably called Mozin: and according to the Chinese histories, it was divided into 55 provinces or districts. In 658, the sovereign of Japan sent a fleet hither with troops, who conquered part of the inhabitants, then divided into three races, one of which was characterised as savage. The Japanese had occasion to repress the natives in 762, when a great stone inscribed with their respective boundaries was erected, which still subsisted in 1720. But the proper history of Jesso is considered as commencing in 1443, when Fakeda Noboe Firo crossing the straits, subdued one half of the island, while the other half submitted to him; and his descendants still inherit the government of it. On occasion of a revolt previous to 1652, which Japanese forces were employed to quell, that nation perhaps first gained a correct knowledge of the country and its inhabitants, who are now driven towards the coast. Before this period, however, Europeans, animated by the desire of propagating their religious opinions, had reached that remote territory. Whether Froes the Portuguese missionary, who gives the earliest account of the natives in 1565, had been in the island, is not evident; but other two missionaries of the same nation, J. Caravaglio, and Jerome de Angelis, were certainly at Matzumay in 1620 and 1621. The people were then represented nearly the same as at present, only very warlike, and much dreaded by the Japanese. The murder of these two missionaries soon after, upon the proscription of the Christian doctrines in Japan, terminated a source of information, which added so much to the geographical knowledge of different Asiatic countries. The loss was in some respects indemnified by the transient observations of successive mariners, which, conjoined to the writings of the Japanese, have illustrated the nature of Jesso, and the manners of its inhabitants. It is singular, however, and ought not to escape notice, that Saris, an English navigator of the beginning of the 17th century, was sufficiently aware of the insular nature of Jesso, its distance from Japan, the Straits of Sangar, and the position of Matzumay, from the information of the Japanese, which were all the subjects of doubt in Britain nearly 200 years later. Indeed, the accuracy of some early navigators is surprising, and there is a general coincidence between their narratives regarding the natives of Jesso, and those which the Japanese obtained somewhat more recently. (*c*)

Jessop.

JESSOP, William. This able engineer and excellent man was born January 12, O.S. 1745, at Plymouth dock, where he was educated. After making some progress in the classics, he acquired a perfect knowledge of the French language, and a considerable share of mathematical science. He early discovered a propensity to mechanical pursuits, and possessing a dexterity of working in wood and metals, he constructed with facility such articles as juvenile projects occasionally required; and his family are now in possession of a tolerably good violoncello of his workmanship when a boy.

These early dispositions recommended him to the notice of Mr Smeaton, then employed in rebuilding the Eddystone light-house, who confirmed his desire of learning the profession of a civil engineer; and he accordingly entered regularly into Mr Smeaton's service, under articles for seven years. This event not only afforded opportunities of employing his talents in a way suited to his natural inclination, but was the means of acquiring the friendship of an able and judicious man, who was well qualified to form his judgment and direct his labours.

Mr Smeaton having, after the completion of the Eddystone light-house, full employment as a civil engineer, his pupil of course benefited by the surveying, investigating, and executing the various works comprehended in such extensive practice. The construction of mills, drainages, harbours, and bridges, and the improvement of river navigations, (as may be seen in Mr Smeaton's reports,) during his seven years regular service, afforded an ample field for acquiring useful knowledge and practical skill. Even in canal making, the repeated surveys, discussions, and progressive practical operations during the execution of the inland navigation between the rivers Forth and Clyde in Scotland, which was under Mr Smeaton's direction, enabled him to obtain, at an early period of life, competent information upon an important part of his profession, which was at that time almost new in British engineering.

The advantages which Mr Jessop thus derived from Mr Smeaton were certainly great; yet there is reason to believe, that his early and constant connection with this eminent engineer, created a degree of timidity in the exercise of his own talents; for we have good authority for stating, that, for some years after the expiration of his articled service, he was almost unwilling to undertake business on his own account. He therefore continued to live with Mr Smeaton, and to act under his immediate direction, and, even when occasionally engaged in business for himself, he took no step without consulting his preceptor. This conduct may, no doubt, be partly attributed to his having become necessary to Mr Smeaton, and to the uninterrupted mutual confidence and esteem which always subsisted between them.

In 1773, he was appointed engineer to the Aire and Calder River navigation in Yorkshire, which, (according to a memorandum in our possession) he states as having found with an income of only £5000 a year, whereas twenty-five years afterwards he left it in the receipt of £30,000 per annum. For several years the improvement of river navigations and drainages constituted his chief employment, though he was also on several occasions consulted in regard to bridges and harbours. In the year 1783 he was appointed engineer for directing the improvements upon the river Trent, in which capacity he continued to act during the rest of his life. He made several surveys and reports for improving the rivers Severne, Mersey, and Irwell; and also the upper part of the Thames.

After Mr Smeaton withdrew from business, Mr Jessop stood at the head of his profession: In the prime of life, and with a sufficient fund of knowledge and experience, his talents became eminently useful during the rapid progress which, at this time, inland navigation made in England. To enumerate the objects of his labours, from the year 1780 to 1800, would be to give a list of nearly all the improvements, of this kind, which were projected and executed during that period: But as this would exceed our prescribed limits, we shall here only observe that the map of the canals in the counties of Derby, Nottingham, Leicester, and Lincoln, were planned and executed under his direction, as was likewise the grand junction canal which connects the midland counties with the metropolis. Besides these, he was occasionally consulted in regard to most of the other canals which were then carrying on in other parts of the kingdom. For several years, previous to his death, he acted jointly with Mr Telford in conducting the great Caledonian canal in the north of Scotland, and that engineer embraced every opportunity of acknowledging, in the warmest manner, the advantages and satisfaction which he derived from the able, upright, and liberal conduct of his enlightened colleague and friend.

In consequence of Mr Jessop's merited reputation, he was consulted respecting the inland navigation of the sister kingdom, which was for many years conducted solely under his direction. The leading arrangements were then made, in order to establish a water communication from the city of Dublin on the east, to the river Shannon in the interior, and by it to Limerick on the west; besides various collateral branches to the southern and northern parts of that fine island. The principal and most difficult operations required to accomplish these desirable objects, were performed under his direction, and the whole put into a state of progress, which afterwards only required to be regulated by the financial resources and growing demands of that rising country.

In regard to harbours, besides many of comparatively inferior importance, which we have not room to enumerate, the great canal and magnificent West India docks in the Isle of Dogs; the extensive improvements in the ports of Bristol, Hull, and Dublin, were planned and executed under his direction. These undertakings, upon an unexampled scale of magnitude and perfection, afford unequivocal evidence of his abilities as an engineer, and at the same time formed a valuable school for others who had occasion to construct similar works.

From being scarcely of sufficient importance to constitute a separate profession when he entered into it, works requiring the attention of a civil engineer, were, in a short time, so greatly increased, that Mr Jessop found that the most unremitting exertions were unequal to the demands upon his services; he, therefore, in the year 1785, introduced Mr Rennie as engineer to the Lancaster canal. This selection is a striking evidence of his discernment of human character, and although as the demand about that time became urgent, such natural talents and assiduity must ultimately have acquired distinction, yet their progress was not a little facilitated by the long continued aid of so experienced and enlightened a friend.

The preceding narrative contains only a rapid sketch of the professional career of this valuable man, who departed this life on the 18th Nov. 1814.

It will be evident to the reader, that in the course of discussing the important article *Inland* NAVIGATION, we shall have frequent opportunities of stating more at length the share that Mr Jessop had in the public works which are here only slightly alluded to, and also the peculiarities in his mode of practice, as well as the particular benefits for which his profession was indebted to him.

His mind was comprehensive, inventive, and sincere. At the age of threescore his mental energies were unabated. Unshackled by prejudices, he retained a youthful ardour for professional improvements; and he would even then not unfrequently display a degree of jealousy, lest a more perfect mode was possible. He constantly devoted his whole mind to the subject before him, and from which all personal considerations seemed excluded. Under these impressions his uniform aim was to accomplish his purposes by the simplest and most economical means: these he sometimes carried to a length to which the average talents of mankind could not always do justice in the execution; but he invariably disdained to screen personal responsibility by unnecessary expenditure, upon the grounds, that it was the business of an engineer, and what ought chiefly to distinguish him from the common workman, to effect his purposes rather by ingenuity of construction, than quantity of materials: that it was an imperative duty rather to risk occasional partial failures from imperfect workmanship, than uniformly to persevere in an unpardonable waste of capital; and that no clamour of ignorance, or prejudice, or consideration of personal interest, should for a moment deter him from this conduct.

His discerning and ingenious mind led him to found his practice upon observation and just principles rather than precedent. In the important articles of Locks, Wharfs, and Retaining Walls, he introduced an entirely new form, composed of nearly one half the quantity of materials employed by the French and early English engineers; he contrived an excellent method of draining morasses and boggy land, more especially for the purpose of constructing a navigable canal through it; he communicated very judicious views respecting the management of flood waters; he seized with eagerness the idea of acquiring an expeditious mode of conveying heavy materials by iron rail roads; and was particularly zealous for the general use of cylindrical broad wheels upon roads composed of gravel. But all these matters, as has been already observed, will be discussed under their proper heads; our intention in mentioning them at present being merely to exhibit the general tenor of Mr Jessop's mind and conduct.

Besides these extensive pursuits in the British islands, his reputation as an engineer led to his being consulted respecting a proposed canal in Spain. What the practical result was, in that distracted and feeble kingdom, it is easy to conjecture. He was also applied to by the American states, to select a properly qualified person for investigating and arranging several proposed inland navigations in that extensive region. In consequence of this, Mr Weston, a very ingenious and well-informed person, was for several years employed in North America; but we suspect that some centuries must yet elapse, before the introduction of this expensive improvement can, with propriety become general in that infant country.

Like most men of truly great minds, his manners were simple; when disengaged from business, and in the company of intimate friends, he not unfrequently displayed a playfulness of disposition, and a fund of entertaining anecdotes. Totally free of all envy and jealousy of professional rivalship, his proceedings in business were free from all pomp and mysticism, and persons of merit never failed in obtaining his friendship and encouragement. Although indefatigable in performing all the duties of an active life, the writer of this article, who for more than twenty years enjoyed his uninterrupted intimacy, has heard it said that he had a natural tendency to indolence; no symptom of it, however, could ever be discovered in his conduct, but rather, as has already been noticed, a degree of anxiety to be of the utmost service to his employers, and to render as perfect as possible the works under his consideration.

A mind thus constituted, and exercising the profession of a civil engineer, was, as might be expected, never behind in regard to physical knowledge and experimental philosophy: His acquirements in these branches of knowledge, joined to his well-earned reputation, led to intimacy with eminent persons of similar characters, such as the celebrated Mr Watt and Dr Franklin. For an acquaintance with the latter he was indebted to an accidental discovery, made as early as the year 1772, with regard to the repelling property of oil on water, and which the Doctor mentions in his works as having been communicated to him by an ingenious pupil of Mr Smeaton.

Mr Jessop has not appeared before the public in the character of an author; for although many of his reports were printed, yet as this was done at the expence of private companies, and as they were not exposed to sale, they are of course in the hands of few. As he was always perfectly master of the subject, his mode of treating it was singularly distinct, comprehensive, and laconic.

Founder.

JESUITS, or the Society of Jesus, one of the most celebrated monastic orders of the Romish church, was founded in the year 1540 by Ignatius Loyola. This extraordinary person was a native of Biscay; and while serving as an officer in the army of Ferdinand V. of Spain, was dangerously wounded in the defence of Pampeluna in 1521. During the progress of a lingering cure, he happened to have no other amusement than what he found in reading the lives of the saints. The perusal of their history inspired his enthusiastic and ambitious mind with an ardent desire of emulating their fabulous exploits. Forsaking the military for the ecclesiastical profession, he engaged himself in the wildest and most extravagant adventures, as the knight of the blessed Virgin. After performing a pilgrimage to the Holy Land, and pursuing a multitude of visionary schemes, he returned to prosecute his theological studies in the universities of Spain, when he was about thirty-three years of age. He next went to Paris, where he collected a small number of associates; and, prompted by his fanatical spirit or the love of distinction, began to conceive the establishment of a new religious order. He produced a plan of its constitutions and laws, which he affirmed to have been suggested by the immediate inspiration of heaven, and applied to the Roman pontiff (Paul III.) for the sanction of his authority to confirm the institution. The Pope referred the petition to a committee of cardinals; and, upon their representing the proposed establishment to be unnecessary and dangerous, refused to grant his approbation. Loyola, however, soon found means to remove the scruples of the court of Rome. He proposed, that the members of his society, besides the usual vows of poverty, chastity, and monastic obedience, should take a fourth vow of subserviency to the Pope, binding themselves, without requiring reward or support, to go wherever he should direct for the service of the church, and to obey his mandate in every part of the globe. At a time when the papal authority had received so severe a shock from the progress of the Reformation, and was still exposed to the most powerful attacks in every quarter, this was an offer too tempting to be resisted. The reigning pontiff, though naturally cautious, and though scarcely capable, without the spirit of prophecy, of foreseeing all the advantages to be derived from the services of this nascent order, yet clearly perceiving the benefit of multiplying the number of his devoted servants, instantly confirmed by his bull the institution of the Jesuits, granted the most ample privileges to the members of the society, and appointed Loyola to be the first general of the order.

Object of the Society.

The simple and primary object of the society was to establish a spiritual dominion over the minds of men, of which the Pope should appear as the ostensible head, while the real power should reside with themselves. To accomplish this object, the whole constitution and policy of the order were singularly adapted, and exhibited various peculiarities which distinguished it from all other monastic orders. The immediate design of every other religious society was to separate its members from the world; that of the Jesuits to render them masters of the world. The inmate of the convent devoted himself to work out his own salvation by extraordinary acts of devotion and self-denial; the follower of Loyola considered himself as plunging into all the bustle of secular affairs, to maintain the interests of the Romish church. The monk was a retired devotee of heaven; the Jesuit a chosen soldier of the Pope. That the members of the new order might have full leisure for this active service, they were exempted from the usual functions of other monks. They were not required to spend their time in the long ceremonial offices and numberless mummeries of the Romish worship. They attended no processions, and practised no austerities. They neither chaunted nor prayed. "They cannot sing," said their enemies, "for birds of prey never do." They were sent forth to watch every transaction of the world which might appear to affect the interests of religion, and were especially enjoined to study the dispositions and cultivate the friendship of persons in the higher ranks. Nothing could be imagined more open and liberal than the external aspect of the institution, yet nothing could be more strict and secret than its internal organization. The gates of the society were thrown open to the whole world, as if there were nothing in its nature to dread disclosure. Men of every description were invited to enter, and talents of every kind were drawn together. It was a company, such as had never yet appeared, of which all mankind might be free at pleasure, but of which every member became in reality an irredeemable slave. Other religious orders were in a manner voluntary associations, of which the executive authority might be vested in certain heads; but whatever affected the whole body as an act of legislation, was regulated by the common suffrage of all its members. Loyola, however, influenced perhaps by the notions of implicit obedience which he had derived from his military profession, resolved that the government of the Jesuits should be absolutely mo-

Form and constitution of the order.

narchical. A general, chosen for life by deputies from the several provinces, possessed supreme and independent power, extending to every person, and applying to every case. By his sole authority he nominated or removed every officer employed in the government of the society. He administered at pleasure the revenues of the order; and disposed of every member by his uncontroulable mandate, assigning whatever service, and imposing whatever task he pleased. To his commands they were required not only to yield outward obedience, but to resign to his direction the inclinations of their wills, and the sentiments of their understandings. Every member of the order, the instant that he entered its pale, surrendered all freedom of thought and action; and every personal feeling was superseded by the interests of that body to which he had attached himself. He went wherever he was ordered; he performed whatever he was commanded; he suffered whatever he was enjoined; he became a mere passive instrument, incapable of resistance. The gradation of ranks was only a gradation in slavery; and so perfect a despotism over a large body of men, dispersed over the face of the earth, was never before realised. To render the subordination more complete, and to enable the general to avail himself to the utmost of his absolute dominion, he was provided with effectual means of perfectly ascertaining the characters and abilities of the agents under his controul. Every novice, who offered himself as a candidate for admission into the order, was required to *manifest his conscience* to the superior, or to a person of his appointment; and not only to confess his defects and vices, but to discover the inclinations, passions, and bent of his soul. This manifestation was renewed every sixth month during the novitiate, which was of considerable length; and every member was also constituted a spy upon the candidates, whose words and actions, and every thing of importance concerning them, he was bound to disclose to the superior. They were required, under this scrutiny, to pass through several gradations of rank, and to have attained the full age of thirty-three years, before they were permitted to take the final vows, and to become professed members. The superiors, under whose immediate inspection they were placed, were thus thoroughly acquainted with their dispositions and talents; and the most minute details of every one's character and capabilities were regularly transmitted to the head office at Rome. These reports were digested and entered into registers, where the general could survey at one view the state of the society in every quarter of the world; the qualifications and talents of its members; and the kind of instruments awaiting his selection for any department in the service. The number of these reports, from the whole thirty-seven provinces of the order, have been calculated at 6584 annually. Besides these, there may be "extraordinary letters," or such as are sent by the monitors or spies in each house; and the provinces were farther bound to state the civil and political circumstances of the various countries where they had their residence. These statements, when relating to matters of importance, were conveyed by a particular cypher known only to the general. The situation and interests of every department were thus intimately known by the head of the whole body; and the employment of every individual member was precisely adapted to his faculties. The meanest talents were in requisition; and, according to their own expression, "the Jesuits had missionaries for the villages, and martyrs for the Indians." There was thus a peculiar energy imparted to the operations of this singular society; which has been compared to a system of mechanism, containing the greatest possible quantity of power distributed to the greatest possible advantage. "The Jesuits," it was said with justice, "are a naked sword, whose hilt is at Rome."

Its maxims and spirit.

The maxims of policy adopted by this celebrated society were, like its constitution, remarkable for their union of laxity and rigour. Nothing could divert them from their original object; and no means were ever scrupled, which promised to aid its accomplishment. They were in no degree shackled by prejudice, superstition, or real religion. Expediency, in its most simple and licentious form, was the basis of their morals, and their principles and practices were uniformly accommodated to the circumstances in which they were placed; and even their bigotry, obdurate as it was, never appears to have interfered with their interests. The paramount and characteristic principle of the order, from which none of its members ever swerved, was simply this, that its interests were to be promoted by all possible means, at all possible expences. In order to acquire more easily an ascendancy over persons of rank and power, they propagated a system of the most relaxed morality, which accommodated itself to the passions of men, justified their vices, tolerated their imperfections, and authorised almost every action, which the most audacious or crafty politician would wish to perpetrate. To persons of stricter principles they studied to recommend themselves by the purity of their lives, and sometimes by the austerity of their doctrines. While sufficiently compliant in the treatment of immoral practices, they were generally rigidly severe in exacting a strict orthodoxy in opinions. "They are a sort of people," said the Abbé Boileau, "who lengthen the creed and shorten the decalogue."

Missions.

They adopted the same spirit of accommodation in their missionary undertakings; and their Christianity, cameleon-like, readily assumed the colour of every region, where it happened to be introduced. They freely permitted their converts to retain a full proportion of the old superstitions, and suppressed without hesitation any point in the new faith, which was likely to bear hard on their prejudices, or propensities. They proceeded to still greater lengths; and, besides suppressing the truths of revelation, devised the most absurd falsehoods, to be used for attracting disciples, or even to be taught as parts of Christianity. One of them, in India, produced a pedigree to prove his own descent from Brama; and another in America assured a native chief that Christ had been a valiant and victorious warrior, who, in the space of three years, had scalped an incredible number of men, women, and children. It was in fact their own authority, not the authority of true religion, which they wished to establish; and Christianity was generally as little known, when they quitted the foreign scenes of their labours as when they entered them.

Secret rules.

But the most singular regulations, which principally contributed to extend the power of the Jesuits, and to form that enterprising and intriguing spirit by which they were distinguished, were long unknown to the rest of mankind, and were concealed with a degree of care, which might alone have excited the worst suspicions of their nature. It was their favourite maxim, from their first institution, never to publish even the ordinary rules and registers of the order. These were preserved, as an impenetrable mystery, not only from strangers, but even from the greater part of their own members. They refused to produce them, when required by courts of justice; and it was not till the public prosecutions against them in Portugal and France, which terminated in their overthrow, had commenced, that the mysterious volumes of the institute were unveiled to the world. But the "*Secreta Monita*,"* or hidden rules of the society, which were not discovered till nearly fifty years after the abolition of the order, and which most unequivocally unfold the detestable nature of the institution, were most anxiously withheld from every eye, except those of the most thoroughly initiated. They were directed to be communicated, even to professed members, with the utmost caution, and then only as the result of personal experience, not as the recorded rules of the institution. In the event also of their falling into the hands of strangers, it was expressly enjoined, that they must be positively denied to be the rules of the society. A few extracts from these hidden precepts will furnish the reader with the best exposure of the spirit and tendency of jesuitism. "Princes and distinguished persons must by all means be so managed (by the members of the society), that they may gain their ear, which will easily secure their hearts; so that all persons will become dependent upon them, and opposition be prevented.—Since ecclesiastics secure the greatest favour by winking at the vices of the great, as in the case of incestuous marriages, &c. such persons must be led to hope, that, through their aid, a dispensation may be obtained from the Pope, which he will no doubt readily grant.—It will further their object, if their members insinuate themselves into foreign embassies, but especially in those to the Pope.—Favour must, above all, be obtained with the dependents and domestics of princes and noblemen, who, by presents and offices of piety, may be so far biassed as to impart intelligence of their employer's inclinations and intentions.—Princesses and females of rank may be gained by women of their bedchambers, who must therefore be particularly addressed, whereby there will be no secrets concealed from their members.—Their confessors must allow greater latitude than those of other orders, in order that their penitents, being allured with such freedom, may relinquish others, and entirely depend on their direction and advice.—Prelates must be engaged to employ the Jesuits both for confessors and advisers. Care must be taken, when princes or prelates found either colleges or parish churches, that the society always have the right of presenting, and that the superior of the Jesuits for the time being be appointed to the cure, so that the whole government of that church and its parishioners may become dependent on the society.—Wherever the governors of academies thwart their designs, or the Catholics or heretics oppose their foundations, they must endeavour, by the prelates, to secure the principal pulpits.—Their members, in directing the great, must seem to have nothing in view but God's glory; and not immediately, but by degrees, interfere in political and secular matters, solemnly affirming, that the administration of public affairs is what they engage in with reluctance, and only as compelled by a sense of duty.—In order to induce rich widows to be liberal to the society, they must be provided with confessors, who may urge their remaining unmarried, by assuring them that they will thereby infallibly secure their salvation, and effectually escape the pains of purgatory.—That the widow may dispose of her property to the society, she must be told of those who have devoted themselves to the service of God, and be led to expect canonization from the court of Rome. Confessors must also enquire of their penitents what family, relations, friends, and estates they possess, and what they have in expectancy, as also their intentions, which they must endeavour to mould in favour of the society. Such members as make a scruple of acquiring riches for the society must be dismissed; and if they appeal to the provincials, they must not be heard, but pressed with the statute, which commands implicit obedience from all.—Such as retain a love for other orders, for the poor, or their relations, must be dismissed, since they are likely to prove of little service.—All, before dismission, must be prevailed upon to subscribe and make an oath, that they will never, directly or indirectly, either write or speak any thing to the disadvantage of the order; and the superiors must keep an account of the sins, failings, and vices, which they formerly confessed, to be used against them, if occasion requires, in order to prevent their future advancement in life; and noblemen and prelates, with whom they may have credit, must be prevailed upon to deny them their protection.—All must be caressed, who are distinguished either for their talents, rank, or wealth, especially if they have friends attached to the society, or possessed of power; such must be sent to Rome, or some celebrated university, for study; but, if they prefer the provinces, the professors must inveigle them into a surrender of their effects to the society, and the superiors must shew a particular regard to such as have allured any promising youths into the society. The preceptors must not chastise or keep in subjection young men of good genius, agreeable persons, and noble families, like their other pupils: they must be won by presents, and the indulgence of liberties peculiar to their age; but on other occasions, especially in exhortations, they must be terrified with threats of eternal punishment, unless they obey the heavenly invitation of joining the society. If any member expects a bishopric or other dignity, he must take an additional vow always to think and speak honourably of the society; never to have a confessor who is not a Jesuit; nor determine any affair of moment, without first consulting the society. The society will contribute much to its own advantage, by fomenting and heightening (but with caution and secrecy) the animosities that arise among princes and great men, in order that they may weaken each other."

History and progress of the society.

These detestable objects and principles, however, were long an impenetrable secret; and the professed intention of the new order, was to promote with unequalled and unfettered zeal the salvation of mankind. Its progress, nevertheless, was at first remarkably slow. Charles V. who is supposed, with his usual sagacity, to have discerned its dangerous tendency, rather checked than encouraged its advancement; and the universities of France resisted its introduction into that kingdom. Thus, roused by obstacles, and obliged to find resources within themselves, the Jesuits brought all their talents and devices into action. They applied themselves to every useful function and curious art; and neither neglected nor despised any mode, however humble, of

---

* These and other institutions, which contributed most essentially to the power and permanence of the society, are attributed to the genius of Laynez and Aquaviva, the two generals who succeeded Loyola, and who were far superior to their fanatical master in the science of government and the knowledge of human nature.

gaining employment or reputation. The satirist's description of the Greeks in Rome, has been aptly chosen to describe their indefatigable and universal industry.

> *Grammaticus, rhetor, geometres, pictor, aliptes,*
> *Augur, schenobates, medicus, magus, omnia novit*
> *Græculus.*——

They laboured with the greatest assiduity to qualify themselves as the instructors of youth; and succeeded, at length, in supplanting their opponents in every Catholic kingdom. They aimed, in the next place, to become the spiritual directors of the higher ranks; and soon established themselves in most of the courts which were attached to the Papal faith, not only as the confessors, but frequently also as the guides and ministers of superstitious princes. The governors of the society, pursuing one uniform system with unwearied perseverance, became entirely successful; and, in the space of half a century, had in a wonderful degree extended the reputation, the number, and influence of the order. When Loyola, in 1540, petitioned the Pope to authorize the institution of the Jesuits, he had only ten disciples; but in 1608, the number amounted to 10,581. Before the expiration of the sixteenth century, they had obtained the chief direction of the education of youth in every Catholic country in Europe, and had become the confessors of almost all its noblest monarchs. They thus formed the minds of men in their youth, and retained the ascendancy over them in their advanced years. They took part in every public measure, and possessed at different periods the direction of the principal courts in Europe. They preserved the highest degree of influence with the Roman pontiffs, as the most zealous champions of their authority; and were equally celebrated by the friends, and dreaded by the adversaries of the Catholic faith, as the ablest and most enterprising order in the church. In 1710, they possessed 24 professed houses, 59 houses of probation, 340 residences, 612 colleges, 200 missions, 150 seminaries, and 19,998 members.

Its power and wealth.

In spite of their vow of poverty, their wealth increased with their power; and they soon rivalled, in the extent and value of their possessions, the most opulent monastic fraternities. Besides the sources of wealth common to all the regular clergy, they possessed one peculiar to themselves. Under the specious pretext of facilitating the success and support of their mission, they obtained a special license from the court of Rome to trade with the nations whom they laboured to convert; and though these mercantile schemes tended ultimately to accelerate their ruin, they proved, during a century and a half, a most lucrative source of property and influence. Besides carrying on an extensive commerce both in the East and West Indies, and opening warehouses in different parts of Europe for the purpose of vending their commodities, they aimed at obtaining settlements, and reigning as sovereigns. It was in this latter capacity, unsuitable as it may seem to their whole character, that they exhibited the most wonderful display of their abilities, and contributed most essentially to the benefit of the human species.

Its establishments in South America.

About the beginning of the 17th century, they obtained from the court of Madrid the grant of the large and fertile province of Paraguay, which stretches across the southern continent of America, from the mountains of Potosi to the banks of the river La Plata; and, after every deduction which can reasonably be made from their own accounts of their establishment, enough will remain to excite the astonishment and applause of mankind. They found the inhabitants in the first stage of society, ignorant of the arts of life, and unacquainted with the first principles of subordination. They applied themselves to instruct and civilize these savage tribes. They commenced their labours, by collecting about fifty families of wandering Indians, whom they converted and settled in a small township. They taught them to build houses, to cultivate the ground, and to rear tame animals; trained them to arts and manufactures, and brought them to relish the blessings of security and order. By a wise and humane policy, they gradually attracted new subjects and converts; till at last they formed a powerful and well organized state of 300,000 families. Over these they exercised a mild and patriarchal government, and their subjects, docile and grateful, revered their benefactors as divinities. The country was divided into 47 districts, over each of which a Jesuit presided. A few magistrates, chosen by the Indians themselves, assisted in every town to secure obedience to the laws. In other respects all the members of the community were, as one family, on a footing of perfect equality, and possessed all things in common. Every individual was obliged to labour for the public, and the fruits of their industry were deposited in common-store houses, from which every person received whatever was necessary for the supply of his wants. Punishments were rare, and always of the mildest description, such as an admonition from the Jesuit, a slight mark of disgrace, or at most a few lashes with a whip. Industry was universal, but wealth and want were equally unknown; and most of those passions, which disturb the peace of society, were deprived of every opportunity to operate. Even the elegant arts began by degrees to appear, and full protection was provided against every invader. An army of 60,000 men was completely armed and regularly disciplined, consisting of cavalry, infantry, artillery, and well provided with magazines of all the implements of war. The Indians of Paraguay, in short, under the government of the Jesuits, were an innocent and happy people, civilized without being corrupted, and yielding with entire contentment the most perfect submission to an absolute but equitable government. Yet, even in this most meritorious effort for the welfare of mankind, the peculiar spirit of the order was sufficiently discernible. In order to preserve their influence, they found it necessary to keep their subjects in a state of comparative ignorance; and, besides prohibiting all intercourse with the adjacent settlements of the Spaniards and Portuguese, they endeavoured to inspire them with a hatred and contempt of those nations. They prevented their subjects from learning any language, except a native dialect, (the Guarani,) which they endeavoured to improve as a general standard, and plainly aimed at establishing an independent empire, subject only to their order, which could scarcely have failed, from its excellent constitution and police, to have extended its dominion over all the southern continent of America.

Reverses and overthrow of the society.

Though the power of the Jesuits had become so extensive, and though their interests generally prospered during a period of more than two centuries, their progress was by no means uninterrupted; and, by their own misconduct, they soon excited the most formidable counteractions. Scarcely had they effected their establishment in France, in defiance of the parliaments and universities, when their existence was endangered by the fanaticism of their own members. John Chastel, one of their pupils, made an attempt upon the life of Henry IV.; and Father Guiscard, another of the order, was convicted of composing writings favourable to regicide. The parliaments seized the moment of their disgrace, and procured their banishment from every part of the kingdom, except the provinces of Bourdeaux and Toulouse. From these rallying points, they speedily extended their intrigues in every quarter, and in a few years obtained their re-establishment. Even Henry, either dreading their power, or pleased with the exculpation of his licentious habits, which he found in their flexible system of morality, became their patron, and selected one of their number as his confessor. They were favoured by Louis XIII. and his minister Richelieu, on account of their literary exertions; but it was in the succeeding reign of Louis XIV. that they reached the summit of their prosperity. The Fathers La Chaise and Le Teltier, were successively confessors to the king; and did not fail to employ their influence for the interest of their order; but the latter carried on his projects with so blind and fiery a zeal, that one of the Jesuits is reported to have said of him, "he drives at such a rate, that he will overturn us all." The Jansenists were peculiarly the objects of his machinations, and he rested not till he had accomplished the destruction of their celebrated college and convent at Port Royal. Before the fall, however, of this honoured seminary, a shaft from its bow had reached the heart of its proud oppressor. The "Provincial Letters of Pascal" had been published, in which the quibbling morality and unintelligible metaphysics of the Jesuits were exposed in a strain of inimitable humour, and a style of unrivalled elegance.[*] The impression which they produced was wide and deep, and gradually sapped the foundation of public opinion, on which the power of the order had hitherto rested. Under the regency of the Duke of Orleans, the Jesuits, and all theological personages and principles were disregarded with atheistical superciliousness; but under Louis XV. they partly recovered their influence at court, which, even under Cardinal Fleury, they retained in a considerable degree. But they soon revived the odium of the public by their intolerant treatment of the Jansenists, and probably accelerated their ruin by refusing, from political rather than religious scruples, to undertake the spiritual guidance of Madame de la Pompadour, as well as by imprudently attacking the authors of the *Encyclopedie*. Voltaire directed against them all the powers of his ridicule, and finished the piece which Pascal had sketched. Their power was brought to a very low ebb, when the war of 1756 broke out, which occasioned the famous law-suit that led to their final overthrow. By that time the society had indicated many symptoms of decay, both in point of talents and activity, and had rendered themselves at once contemptible and odious. They had disgusted the court by their scruples, irritated the philosophers by their clamours, exasperated the other religious orders by their persecutions, and alienated the public by their long and insolent domination. A reasonable pretext was all that was wanted to put down a sect, which had long ceased to be either popular or formidable. The opportunity was soon furnished by their own impudent obstinacy. The war recently commenced, had occasioned great losses in their trade with Martinico, the weight of which would have fallen in part upon the society's correspondents at Lyons and Marseilles. These merchants, however, alleged that the Jesuits in France were responsible for the debts of their missionaries in America, and insisted upon being indemnified from the funds of the order. The claim was resisted, and a law suit commenced, which the Jesuits, by virtue of their privilege, removed from the provincial parliament to the great chamber at Paris. This measure rendered the dispute and their defeat subjects of more general notoriety. They were condemned to pay large sums to the adverse party, and prohibited thenceforth from meddling in commercial concerns. The sources of their wealth were thus diminished, and their enemies encouraged to renewed attacks. The questions at issue in the commercial dispute, had given the magistrates a plausible occasion for demanding to inspect the constitutions of the society; and, in a luckless hour for themselves, they consented to produce their books. The parliament instantly saw and seized the advantage which they had gained, and resolved to effect the destruction of the order. By an arret of the 11th August 1761, the Jesuits were required to appear at the end of a year to receive judgment on their constitution, which, it was now discovered, had never been approved with the requisite forms. In the mean time the king of Portugal was assassinated; and Carvalho, the minister, who detested the Jesuits, found means to load them with the odium of the crime. Malagrida, and a few more of these fathers, were charged with advising and absolving the assassins, and having been found guilty, were condemned to the stake. The rest were banished with every brand of infamy, and were treated with the most iniquitous cruelty. They were persecuted without discrimination, robbed of their property without pity, and embarked for Italy without previous preparation; so that no provision having been made for their reception, they were literally left to perish with hunger in their vessels. These incidents prepared the way for a similar catastrophe in France. During the year allotted for the investigation of their rules and records, the court evinced a disposition to protect them, and the bishops declared unanimously in their favour; but an unforeseen public calamity rendered it necessary to appease the nation by some acceptable measure; and the Jesuits, after all, are supposed to have been sacrificed more as a trick of state than as an act of justice.

In March 1762, the French court received intelligence of the capture of Martinico by the British; and dreading a storm of public indignation, resolved to divert the exasperated feelings of the nation, by yielding the Jesuits to their impending fate. On the 6th of August 1762, their institute was condemned by the parliament, as contrary to the laws of the state, to the obedience due to the sovereign, and to the welfare of the kingdom. The order was dissolved, and their effects alienated. But still the members, though no longer dressed in their religious habit, continued to hover about the court; and, had they preserved their original cautious and patient policy, might have succeeded in recovering their privileges. But former successes inspired them with a fatal confidence. One of the archbishops, indignant that the parliament should presume to dispense with ecclesiastical vows, issued a mandate in favour of the Jesuits, and the fathers were accused of having employed themselves too industriously in the circulation of this paper. The parliament took the alarm, and pronounced a decree, that every Jesuit, whether professor or novice, should, within eight days, make oath that he renounced the institution, or quit the kingdom. In a body, whose moral principles were so

---

[*] See also *La Morale Pratique des Jesuits*, per Arnauld.

relaxed, and whose members, while it existed, scrupled no subtilties in promoting its interests, it is a remarkable circumstance, that, as secularized individuals, they acted in this instance with strict integrity, and refused the alternative of the oath. They were therefore ordered to quit the kingdom, and this judgment was executed with the utmost rigour. The poor, the aged, the sick, were included in the general prescription. But in certain quarters, where the provincial parliaments had not decided against them, Jesuits still subsisted; and a royal edict was afterwards promulgated, which formally abolished the society in France, but permitted its members to reside within the kingdom under certain restrictions. *

In Spain, where they conceived their establishment to be perfectly secure, they experienced an overthrow equally complete, and much more unexpected. The necessary measures were concerted under the direction of De Choiseul, by the Marquis D'Ossun, the French ambassador at Madrid, with Charles III. King of Spain, and his prime minister the Count D'Aranda. The execution of their purpose was as sudden as their plans had been secret. At midnight, (March 31st 1767), large bodies of military surrounded the six colleges of the Jesuits in Madrid, forced the gates, secured the bells, collected the fathers in the refectory, and read to them the king's order for their instant transportation. They were immediately put into carriages, previously placed at proper stations; and were on their way to Carthagena before the inhabitants of the city had any intelligence of the transaction. Three days afterwards, the same measures were adopted with regard to every other college of the order in the kingdom, and ships having been provided at the different sea-ports, they were all embarked for the ecclesiastical states in Italy. All their property was confiscated, and a small pension assigned to each individual as long as he should reside in a place appointed, and satisfy the Spanish court as to his peaceable demeanour. All correspondence with the Jesuits was prohibited, and the strictest silence on the subject of their expulsion was enjoined under penalties of high treason. A similar seizure and deportation took place in the Indies, and an immense property was acquired by the government. Many crimes and plots were laid to the charge of the order; but whatever may have been their demerit, the punishment was too summary to admit of justification; and many innocent individuals were subjected to sufferings beyond the deserts even of the guilty. Pope Clement III. prohibited their landing in his dominions; and, after enduring extreme miseries in crowded transports, the survivors, to the number of 2300, were put ashore on Corsica. The example of the King of Spain was immediately followed by Ferdinand VI. of Naples, and soon after by the Prince of Parma. They had been expelled from England in 1604; from Venice in 1606; and from Portugal in 1759, upon the charge of having instigated the families of Tavora and D'Aveiro to assassinate King Joseph I. Frederick the Great of Prussia was the only monarch who shewed a disposition to afford them protection; but, in 1773, the order was entirely suppressed by Pope Clement XIV. who is supposed to have fallen a victim to their vengeance.† In 1801, the society was restored in Russia by the Emperor Paul; and in 1804, by King Ferdinand in Sardinia. In August 1814, a bull was issued by the present Pope, Pius VII. restoring the order to all their former privileges, and calling upon all Catholic princes to afford them protection and encouragement. This act of their revival is expressed in all the solemnity of Papal authority; and even affirmed to be above the recal or revision of any judge with whatever power he may be clothed; but to every enlightened mind it cannot fail to appear as a measure altogether incapable of justification, from any thing either in the history of Jesuitism or in the character of the present times.

General character of the Jesuits.

It would be in vain to deny, that many considerable advantages were derived by mankind from the labours of the Jesuits. Their ardour in the study of ancient literature, and their labours in the instruction of youth, greatly contributed to the progress of polite learning. They have produced a greater number of ingenious authors than all the other religious fraternities taken together; and though there never was known among their order one person who could be said to possess an enlarged philosophical mind, they can boast of many eminent masters in the separate branches of science, many distinguished mathematicians, antiquarians, critics, and even some orators of high reputation. They were in general, also, as individuals, superior in decency, and even purity of manners, to any other class of regular clergy in the church of Rome. Their active and literary spirit furnished, likewise, a most beneficial counteraction to the deadening influence of their contemporary monastic institutions. Even the debased species of Christianity, which they introduced among the savage tribes of America, and the more civilized nations of the East, was infinitely superior, both in its consolations and morals, to the bloody and licentious rites of idolatry. But all these benefits by no means counterbalanced the pernicious effects of their influence and intrigues on the best interests of society.

The essential principles of the institution, viz. that their orders is to be maintained at the expence of society at large, and that the end sanctifies the means, are utterly incompatible with the welfare of any com-

---

* The Duke de Choiseul, the French minister, was a principal agent in procuring their final suppression, and the following origin has been assigned to be the hostility with which he pursued the whole order in every quarter of Europe. The Duke having no employment in the government of France, happened one evening at supper to say something very strong against the Jesuits. Some years afterwards, he was sent ambassador to Rome, where, in the usual routine of his visits in that situation, he called upon the General of the Jesuits, for whose order he professed the highest veneration. "Your Excellence did not always, I fear, think so well of us," replied the General. The Duke, much surprised at this observation, begged to know what reasons he had for thinking so, as he was not conscious that he had ever mentioned the order but in terms of the highest respect. The General, to convince him of the contrary, shewed him an extract from a large register book belonging to the society, in which the particular conversation alluded to, and the day and the year in which it happened, were minuted down. The ambassador blushed, and excused himself as well as he could, and soon went away, resolving within himself, whenever he should become prime minister, to destroy a society that kept up such particular and detailed correspondences, of which it might make use to the detriment of administration and government."—Seward's *Biographiana.*

† It was long a current story at Rome, that this pontiff was accustomed to withdraw in the course of the grand mass to take some refreshment; that a young priest, on one of these occasions, brought chocolate to his Holiness, and immediately withdrew; that the proper officiating priest soon after appeared with another cup, the pope shook his head, as conscious of having received a fatal potion; that he pined from that day of a lingering disease, which reduced his body to the appearance of a skeleton; and that he was known to have said, in allusion to the secret cause of his death, "I am going to eternity, and I know for what."

munity of men. Their system of lax and pliant morality, justifying every vice, and authorizing every atrocity, has left deep and lasting ravages on the face of the moral world. Their zeal to extend the jurisdiction of the court of Rome over every civil government, gave currency to tenets respecting the duty of opposing princes who were hostile to the Catholic faith, which shook the basis of all political allegiance, and loosened the obligations of every human law. Their indefatigable industry, and countless artifices in resisting the progress of reformed religion, perpetuated the most pernicious errors of Popery, and postponed the triumph of tolerant and Christian principles. Whence, then, it may well be asked, whence the recent restoration? What long latent proof has been discovered of the excellence or even the expedience of such an institution? The sentence of their abolition was passed by the senates, and monarchs, and statesmen, and divines, of all religions, and of almost every civilized country in the world. Almost every land has been stained and torn by their crimes; and almost every land bears on its public records the most solemn protests against their existence. Even they who loved popery, but dreaded the atrocities and ambition of Jesuitism; even an infallible pontiff, in his cool judicial capacity, after a most solemn hearing, and in the face of its most powerful advocates, pronounced its condemnation. What new witness has appeared to testify its virtues? What adequate cause been made out for its revival? If an instrument is wanted, (says an able opponent of Jesuitism*), which may at once quench the flame of charity—throw us back in the career of ages—sow the seeds of everlasting division—lay a train which is to explode in the citadel of truth, and overturn her sacred towers—we venture confidently to affirm that Jesuitism is that instrument. But, as for any other advantages either to Protestantism or Popery, it is for the Pope, or any other infallible reasoner, to shew. Till some such superior being shall stoop down to instruct us on this point, and to establish a fact which the Jesuits themselves for two centuries, and by a whole regiment of folios, endeavoured to establish in vain, we must venture to conclude, with our forefathers, with the kings, and queens, and parliaments, and judges, and churches of Europe, and with the infallible Pope Clement XIV. that Jesuitism is a public nuisance; and that he who endeavours to let it loose upon society, is chargeable with high treason against the common interests and happiness of his species." See Robertson's *History of Charles V.* vol. ii. *and the authorities there cited*; D'Alembert's *Narrative of the destruction of the Jesuits*; *A short View of the Polity of the Jesuits in Paraguay*, attributed to the pen of Mr Burke, and to be found in the 1st vol. of *The European Settlements in America*; Southey's *History of Brazil*; Adolphus' *History of England*, vol. i.; Mosheim's *Ecclesiastical History*, vol. iv.; *Christian Observer*, vol. vi.; and *A Brief Account of the Jesuits, &c.* London, 1815. JEWS.

IN the present article, we propose to lay before our readers, in the first place, a brief sketch of the history of the Jews from the period of their return to Jerusalem from Babylon, and the rebuilding of their city and temple under Ezra and Nehemiah, when the scriptures leave off any farther accounts, and when profane historians begin to take notice of them, till the destruction of Jerusalem under Titus;—in the second place, notices of their history since that event, especially such as relate to their history in England;—and lastly, a general view of their opinions, traditions, rites, and ceremonies.

History.
534 B. C.
Nehemiah.

I. In the year 534 B. C. the foundations of the temple at Jerusalem were laid; and after a great many obstacles and delays, it was finished, as related in the books of Ezra and Nehemiah. The last of these chiefs died about the year 409 B. C. He justly may be ranked among the great characters of ancient history. He forsook a place of influence at the most splendid court of Asia to encounter every hardship, actuated by the patriotic and beneficent wish of bestowing independence and happiness upon his poor, ignorant, and wretched countrymen, and of raising them, by moral and religious education, to the rank of a brave, industrious, and comparatively virtuous nation. Before Nehemiah, the Jews were addicted to idolatry, and totally ignorant of a future state; he however succeeded, by a wise and judicious selection of their laws and traditions, and by directing their attention more to practice than to disputation, in rendering them austerely moral, and brave defenders of their independence.

351 B. C.

Still there existed sources of calamity and distress among them; their country was only a province of Syria, subject to the kings of Persia. The Syrian governors, in order to secure and extend their influence and power, conferred the administration of affairs upon the high-priests. The bad effects of this measure soon became apparent, in creating jealousies among those who thought they had a claim to this office. The first public calamity that befel the Jewish nation after their return from Babylon occurred in the year 351 B. C.; when, in consequence of their having offended the king of Persia, he took Jericho, and carried off all the inhabitants captives. When Alexander invaded Persia, they seem to have pursued commerce with such great success, that it appeared to that monarch an object to obtain the settlement of Jewish colonies in his sea ports. He also favoured them in many other respects; but the story of his interview with the high-priest seems of very doubtful credit. On the death of Alexander, Judea, from its locality, lying between Syria and Egypt, was exposed to all the revolutions and wars which his successors waged with each other. After Ptolemy had succeeded in wresting Syria and Phœnicia from Leomedon, he laid siege to Jerusalem. The Jews were prepared for a long and obstinate resistance; but Ptolemy being informed that they would not fight

on their Sabbath, assaulted the city on that day, and easily took it. When this monarch, five years afterwards, was obliged to yield Judea to Antigonus, the latter behaved to the Jews in such a tyrannical manner, that great numbers of them fled into Egypt and Syria, and Judea seemed in danger of being entirely depopulated till it was recovered by Ptolemy in the year 292 B. C. In the reign of Ptolemy Philopater, a dreadful persecution was carried on against them, in consequence of their attempting to prevent that monarch from profaning the temple, by entering into the sanctuary.

Jews favoured by Antiochus, 204 B. C.

Civil discords, 176 B. C.

Judea ravaged by Antiochus, 168 B. C.

On their ready submission, in the year 204 B. C. to Antiochus the Great, they gained such a strong hold on his favour, that he promised to restore Jerusalem to its former splendour, to recall the Jews, and to replace them, as far as possible, in their ancient privileges. He actually granted an exemption of taxes to all the dispersed Jews that would come, within a limited time, to settle in Jerusalem; and he ordered all who were slaves in his dominions to be set free. But the Jews were not long to enjoy this prosperity. About the year 176 B. C. a quarrel happened between the high-priest and the governor of the temple, which was attended with the most fatal consequences, a civil war ensuing, in which many fell on both sides. When Antiochus Epiphanes ascended the throne of Syria, Jason, the high-priest's brother, purchased from that monarch the high-priesthood; and afterwards introduced Grecian customs, and the ceremonies of paganism among the Jews. From this time the service of the temple was neglected, and a general apostacy took place. The power of Jason, however, was not of long continuance; for his brother Menelaus having offered to the Syrian monarch a higher price than Jason gave for the priesthood, and having moreover promised to renounce Judaism, and embrace the religion of the Greeks in all respects, that monarch gave Menelaus a force sufficient to drive Jason out of Jerusalem. Menelaus conducted himself with great tyranny towards the Jews, who complained of him to Antiochus; but that monarch paid no attention to their complaints so long as Menelaus could procure money to bribe him. About the year 170 B. C. Antiochus marched against Jerusalem, in consequence of the Jews having rebelled, and made great rejoicings on the report that he had been killed at the siege of Alexandria. He soon made himself master of the city, where he behaved with such cruelty, that it is supposed, in the course of three days, 40,000 Jews were killed, and as many sold for slaves. Menelaus still retained the protection and favour of the Syrian monarch, and if possible exceeded his former acts of tyranny and cruelty. But the Jews were reserved for yet greater calamities; for, about the year 168 B. C. Antiochus, having been most severely mortified by the Romans, resolved to wreak his vengeance on the Jews. He accordingly dispatched an army of 22,000 men to plunder all their cities, to murder all the men, and to sell the women and children for slaves. The Jews, incapable of resistance, beheld their city taken, their temple profaned, and their religion abolished. About 10,000 of them, who escaped the slaughter, were carried away captive. In order still more effectually to accomplish his purpose, the Syrian monarch ordered the temple to be dedicated to Jupiter Olympius, and his statue to be set up on the altar of burnt-offering. All who refused to come and worship were massacred, or tortured till they complied. Altars, groves, and statues were raised throughout Judea, at which the inhabitants were compelled to worship, while it was instant death to observe the Sabbath, circumcision, or any other of the rites and ceremonies instituted by Moses.

Jews roused by Mattathias. 167 B. C.

The Jews now yielded to despair, when an eminent priest, named Mattathias, had the courage to oppose the orders of the king, and, by his example and exhortations, roused the spirits and the zeal of his countrymen. In the year 167 B. C. Mattathias, finding that his followers daily increased in number, attacked the Syrians and apostate Jews, marching from city to city, overturning the idolatrous altars, and opening the synagogues. He was so successful, that in the space of a year he had extended his reformation throughout a considerable part of Judea, and he could probably have completed it had he not died.

Judas Maccabeus, 163 B. C.

He was succeeded by the famous Judas Maccabeus, who, at the head of 6000 men, made himself master of some of the strongest fortresses in Judea, and after defeating the Syrians in five pitched battles, drove them entirely out of the country, except from a strong fort built over against the temple. In the year 163 B. C. after the death of Antiochus, a peace was concluded upon terms very advantageous to the Jewish nation; but it was not of long continuance. Judas was again successful in five engagements; in the sixth, however, having been abandoned by all his troops except 800, he, together with this gallant band, was slain in the year 161 B. C. Jonathan and Simon, his brothers, succeeded him. The latter drove the Syrian garrison from the fortress of Jerusalem, but was at last treacherously murdered by his son-in-law about 135 B. C.

Alexander Jannæus, 105 B. C.

Rebellion of the Pharisees.

Simon was succeeded by his son Hyrcan, who made himself master of all Palestine, as well as of Samaria and Galilee. He was successful and happy till the last year of his life, when he became involved in a quarrel with the Pharisees, which is supposed to have shortened his days. The factious and turbulent spirit of this sect also proved very troublesome to Alexander Jannæus, who obtained the royal power in the year 105 B. C. and who seems to have been a monarch of great activity, enterprise, and talent. While he was engaged in subduing his foreign enemies, the Pharisees raised a rebellion at home, but this he quashed in the year 86 B. C.; and, by treating them with very great severity, not to say cruelty, he prevented them from again disturbing his reign. Alexander having made several conquests in Syria, died about 79 B. C. He left two sons, Hyrcanus and Aristobulus, but bequeathed the government to his wife as long as she lived. The Pharisees by this time had again put forth their power, and became so turbulent as to render the situation of the queen very unpleasant: they even compelled her to persecute the Sadducees in a most cruel manner. On her death, contests began between her sons: the Pharisees supported Hyrcanus, but his army deserting to Aristobulus, the former was obliged to abandon all title both to the royal and pontifical dignity. His party, notwithstanding, still existed and were active; and having obtained the assistance of the King of Arabia, invaded Judea, defeated Aristobulus, and closely besieged him in Jerusalem. In this situation, the latter called in the Romans, and by their means drove the Arabians out of the country.

After this, both the brothers agreed to constitute Pompey, at that time commander in chief of all the

Pompey interferes in the affairs of Judea.

63 B. C.

Roman forces in the east, the arbitrator of their differences. Pompey had resolved to take the part of Hyrcanus; and Aristobulus, suspecting this, prepared to defend himself against the Romans. On this, the Roman general summoned him to appear before him, which he reluctantly did. Pompey insisted that he should deliver up all the fortified places he possessed. Upon this he fled to Jerusalem, but being quickly followed by Pompey, to prevent hostilities, he promised to pay him a large sum of money. Some troops were accordingly sent to receive the stipulated sum, but they were repulsed by the garrison of Jerusalem. This exasperated Pompey so much, that he immediately marched against that city. The Jews were still so scrupulous, that they would not do any thing on the Sabbath to prevent the besiegers from carrying on their works. The city was therefore taken in the year 63 B. C. Twelve thousand of the inhabitants were slaughtered, and many more put an end to their own lives. Hyrcanus was restored to the dignity of high priest, with the title of prince, but forbidden to assume the title of king, or to extend his territories beyond Judea. The walls of Jerusalem were destroyed, and a Roman governor and garrison were left in it. Aristobulus, and his two sons Alexander and Antigonus, were carried by Pompey to Rome; but Alexander escaped into Judea, and raised an army of 11,500 men. Hyrcanus on this applied to the Romans for assistance: Alexander ventured a battle, but was defeated with considerable loss. After this, his mother contrived to make his peace with the Romans. Judea was at this period divided into five districts, in each of which a separate court of judicature was erected. The first of these was at Jerusalem; the second at Gadara; the third at Amath; the fourth at Jericho; and the fifth at Sephoris in Galilee.

Jews favoured by Cæsar.

Jerusalem taken by the Romans, 37 B. C.

Herod rebuilds the temple. 23 B. C.

The Jews having ingratiated themselves with Cæsar, during the civil wars between him and Pompey, were so highly favoured while he lived, that they could scarcely be said to feel the Roman yoke. After his death, however, great commotions prevailed among them, which were not put down till Herod, who was created King of Judea by Marc Anthony in the year 40 B. C. was firmly established on the throne by the taking of Jerusalem by the Romans in 37 B. C. But the Jews soon found that they had only changed civil commotions for the most dreadful tyranny. The whole conduct of Herod was so cruel, that an attempt was made to destroy him. This, however, did not succeed; and Herod, having discovered the authors of the plot, caused them and their families to be put to death. Shortly after this, however, he regained, in some degree, the confidence and attachment of his subjects, by his generosity to them during a famine. About the year 23 B. C. he rebuilt the temple with great splendour and magnificence. These, however, were only intervals of his cruelty and tyranny. At length, he was seized with a most loathsome and incurable disease, of which he died. He divided his kingdom among his sons in the following manner: To Archelaus, he allotted Judea; to Herod, or Antipas, Galilee and Pirea; and to Philip, Trachonitis, Gaulon, Batanea, and Panias.

Augustus divides Judea.

No sooner was his death known, than tumults, seditions, and insurrections arose. An appeal was made to Augustus, who made the following division of the kingdom: Archelaus had one half, with the title of Ethnarch. His portion contained Judea Proper, Idumea, and Samaria. The remainder was divided between Philip and Herod; the former of whom had Trachonitis, Batanea, and Auranitis, together with a small part of Galilee; the latter had the rest of Galilee, and the countries beyond the Jordan.

Declared a Roman province.

Pontius Pilate appointed governor of Judea. A. D. 16.

A few years after this division, Archelaus was summoned to Rome by the Emperor, in consequence of complaints against his tyranny. His effects were confiscated, himself banished, and a Roman governor appointed over Judea, which was declared a Roman province. The Jews, dissatisfied at this arrangement, and moreover, excited to tumult by the taxes imposed upon them by their new masters, were seldom quiet; their restlessness was increased by their expectation at this time of their Messiah; and, as they anticipated in him a temporal prince, they looked forward to his coming as the era of their emancipation from the Roman yoke, and their restoration to national independance and power. The governors appointed by the Romans were frequently changed, but seldom was the change beneficial to the Jews. About the 16th year of Christ, Pontius Pilate was appointed governor: his administration was one continued scene of rapine, tyranny, and cruelty. Seven years after his condemnation of our Saviour, he was removed from the government, and Agrippa, the grandson of Herod, was raised to the royal dignity. His character and conduct were similar to those of his grandfather, and his death was equally dreadful and singular. On his death, Judea was again declared a Roman province. The governors appointed to rule over it were distinguished for every species of vice; and from them the Jews suffered so much, that many of the inhabitants emigrated. About this time it was computed that there were in Jerusalem between 2,500,000 and 3,000,000 Jews.

War between the Jews and Romans, A. D. 67.

Jerusalem besieged by Titus. A. D. 72.

In the year 67 A. D. that fatal war between the Jews and the Romans commenced, which ended in the destruction of Jerusalem and the dispersion of the Jews. The immediate cause of this war was a dispute between the Jews and the Syrians respecting the city of Cæsarea. Nero decided the question against the former, who immediately took up arms. Dreadful cruelties were committed by both parties, but the Jews suffered most: 20,000 of them were massacred by the Syrians and Romans at Cæsarea; 50,000 at Alexandria; 2000 at Ptolemais, and 3500 at Jerusalem. Soon after these massacres, the Jews obtained some partial and temporary successes, in consequence of which Vespasian was sent into Judea with an army of 60,000 men in the year 68 A. D. His success was great and rapid, while the Jews, instead of uniting to oppose him, and save their country, were divided into two parties: one were for submitting to the Romans, the other opposed all peaceable measures. This dissension was not confined to Jerusalem, but spread through all the cities, towns, and villages of Judea: even houses and families were divided against each other. Jerusalem was the scene of their contentions. The city was filled with butcheries of the most horrid kind. Twelve thousand persons of noble extraction, and in the flower of their age, were put to death by the Zealots, for so that party who were for war with the Romans were called. The Zealots, after having massacred or driven away the opposite party, turned their arms against themselves, till, in the year 72 A. D. Titus advanced at the head of a powerful army against Jerusalem. This for a while suspended their mutual animosities; but they soon returned to them, and thus facilitated the triumph of the Romans.

As Titus wished, if possible, to preserve the city, he sent the besieged offers of peace, but they were rejected; upon which he resolved to carry on the siege with vigour a fortnight after it commenced; a breach was made in the outer wall, by which the Romans entered, the Jews retiring behind the next inclosure. Five days after gaining this advantage, the Romans entered into the second inclosure. Famine and pestilence now raged in the city to a dreadful degree; and these scourges were increased by intestine feuds. As soon as Titus learned their condition, he again offered them peace; but his offer was rejected. Upon this, he caused the city to be surrounded with a strong wall, which, though nearly five miles in circuit, was finished in three days. By means of it, the besieged could not escape, nor receive provisions or succour. Nothing could be more dreadful than the famished condition to which they were now reduced. It was at this juncture, according to Josephus, that a mother butchered and ate her own child. When Titus heard of this horrid deed, he swore he would effect the total extirpation of the city and people. About the end of July, the Romans gained possession of the fortress Antonia, which obliged the Jews to set fire to the galleries which joined it to the temple. The factious in the city, instead of mutually yielding and opposing the enemy, grew more embittered against each other; and one of them actually plundered the temple. On the 8th of August, Titus having in vain endeavoured to save that edifice, ordered the gates of it to be set on fire; but he afterwards caused the fire to be extinguished before the temple itself was destroyed. On the 10th of that month, he determined on a general assault; but before this took place, the temple was set on fire, whether by the Jews or the Roman soldiers is uncertain. Titus in vain endeavoured to extinguish the flames: his soldiers would not obey his orders for that purpose. A dreadful massacre followed soon afterwards, in which many thousands perished. In the meantime, great preparations were making for an attack on the palace, which took place on the 8th, when the city was entered by Titus. The whole number of Jews who perished during this war is computed at nearly 1,500,000. Three castles were still untaken, two of which soon capitulated; but the third, Massador, made a desperate resistance. It was extremely strong; and the Roman general, having in vain tried his engines and battering rams against it, ordered it to be surrounded with a high wall, and the gates to be then set on fire. In this dreadful situation, the commander persuaded the Jews to kill their wives and children, and afterwards to choose ten men by lot which should kill all the rest, and, lastly, one out of these ten to dispatch them and himself, having previously to his own destruction set fire to the place. This was accordingly done. Two women, however, who had concealed themselves, came out, when the Romans were preparing to scale the walls, and acquainted them with the fate of their town's people. Thus ended the Jewish nation and worship in their own country.

Temple burnt.

Jerusalem taken.

History of the Jews in England.

II. It is uncertain at what period the Jews first settled in England. From the preface to Leland's *Collections*, it appears that Mr Richard Waller believed them to have settled here during the government of the Romans. This opinion was founded on the circumstance of a Roman brick having been found at London, having on one side a bas-relief, representing Sampson driving the foxes into a field of corn. From the elegance of the sculpture, and other circumstances, it was inferred that this brick could not be the work of later ages; and if Roman, of Roman Jews, from the subject. However this may be, it is certain that the Jews were numerous in England, so early as the year 740, since the 24th paragraph of the Canonical Excerptions, published by Egbright, Archbishop of York, in that year, forbids any Christians to be present at the Jewish feasts. In a charter of Witglaff, King of Mercia, made to the monks of Croyland, there are confirmed to them not only such lands as had been given to the monastery by the kings of Mercia, but all their possessions whatever, whether they were originally bestowed on them by Christians or Jews. During the feudal ages, the Jews, from their aversion to war, and their love of gain, seem to have been the most opulent, as well as the most polished and enlightened portion of the laity. They were the only bankers of the period. They conducted foreign trade, and in the course of it often visited the countries of southern Europe. Most of the gold and silver ornaments for altars were wrought by them. William Rufus encouraged them to enter into solemn contests with his bishops concerning the true faith; swearing by the faith of St Luke, his favourite oath, that, if the Jews were victorious in the dispute, he would turn Jew himself. Accordingly during his reign there was a public meeting for this disputation, at which the Jews opposed the Christians with so much vigour, promptitude, and acuteness, that the clergy felt considerable anxiety respecting the issue.

Favoured by William Rufus.

Numbers and wealth in the reig of Henry II

Henry II. in the 24th year of his reign, granted a burial-place to the Jews on the outside of every city where they dwelt. At this period, one Joshua, a Jew, furnished the rebels in Ireland with great sums of money; and another Jew of Bury St Edmunds took in pledge certain vessels appropriated to the service of the altar. Such was the confidence they felt either in their numbers or their wealth, that at this time they underrated the highest dignitaries of the church. In the year 1188, the parliament of Northampton proposed to assess the Jews at £60,000, and the Christians at £70,000, towards carrying on a projected war. In the reign of Richard I. the prejudices of the people of England seem to have been for the first time generally and strongly excited against them. A crusade had been resolved on; the populace, roused by the declamations of the clergy, easily turned their zeal against the Jews. In London, their houses were broken open and plundered. On this occasion, three persons only were punished, who through mistake had damaged the houses of Christians. In the space of six months, the persecution of the Jews became general throughout the kingdom. The most dreadful outrage against them was committed at Stamford fair. Here were collected an immense number of the populace, who were preparing to go with the king to the Holy Land. As for this enterprise they had already expended the little property they possessed; they resolved to force the Jews also to contribute their share. With this intention, they attacked them when assembled in great numbers at this fair, and quickly made themselves masters both of their persons and fortunes; the former of which they treated with all kinds of barbarity. A few of them were so fortunate as to obtain shelter in the castle. The king did not endeavour to prevent this outrage, nor did he punish it. At this period, it is supposed by some writers that they invented bills of exchange, since mention seems to be made of them by the name of Starra, (from the Hebrew *Shetar*,) in certain Latin documents of this era. By an edict of Richard I. for registering their

Plundered in the reign of Richard I.

property, it appears that they were still permitted to exercise the liberal professions; this edict ordering that their contracts should be made in the presence of two assigned lawyers who were Jews, two who were Christians, and two public notaries. This king also appointed *Justicers* of the Jews, whose business it was to collect and pay into the exchequer the taxes assessed upon them. The Jews found their situation under Richard so intolerable, that nearly all the wealthier of them emigrated, and there was a consequent defalcation of the revenue. This was so considerable in the reign of John, that that monarch, in the year 1199, used his utmost endeavours to tempt them back to England; not only confirming their ancient privileges, but granting them new ones, particularly that of appointing a high-priest. Upon this, many of them returned; but they were more cruelly plundered than ever. It has been remarked, that Magna Charta sanctions an injustice to this ill-used race, by enacting, that "if any persons have borrowed money of the Jews, more or less, and die before they have paid the debt, the debt shall not increase while the heir is under age;" but, in our opinion, this clause had no reference to the Jews *as Jews*, but merely as money-lenders, and as they were the only money-lenders of that period, they alone are mentioned.

Many emigrate.

Situation under Henry III.

As long as the rage for crusading lasted, the Jews were liable to great indignities and oppression, particularly from those who had performed a pilgrimage to Jerusalem. Against these, Henry III. ordered them to be protected; he also liberated such as were in prison. In order to distinguish them, he directed them to wear upon the fore part of their upper garment two broad stripes of white linen or parchment. It was in this reign that the Archbishop of Canterbury, and the Bishops of Lincoln and Norwich, published injunctions throughout their respective dioceses, that no Christian should presume to have any communication with the Jews, or sell them any provisions, under pain of excommunication. The king, however, interfered in their behalf; and thus rescued them from starving. The prior of Dunstable was more liberal than his superiors; for, about this time, he granted to several Jews liberty to reside on his land, and to enjoy all the privileges which his other vassals enjoyed, in consideration of the annual payment of two silver spoons.

Synagogue built in London. A.D. 1230.

In the year 1230, the Jews took advantage of the protection and favour of Henry, and erected a very costly and magnificent synagogue in London; but the people petitioned the king to take it from them, and have it consecrated, which was accordingly done. In the 18th year of his reign, on a petition of the inhabitants of Newcastle, he granted them the privilege that no Jew should ever reside among them. It was during the reign of Henry that the Lombards settled in England, and by gradually superseding the Jews in the lending of money, and thus rendering them less necessary, paved the way for worse treatment than they had hitherto experienced. To such a pitch of hatred was the prejudice which had been gradually instilled into the people against the Jews arrived, that in 1262, the barons being then opposed to the king, and wishing to bind the citizens of London to their cause, ordered 700 Jews to be slaughtered at once, their houses to be plundered, and their new synagogue burnt. It was however, rebuilt; but in 1270 it was taken from them, on the complaint of the Friars Penitents, that they were not able to make the body of Christ in quiet, on account of the great howlings which the Jews made during their worship.

Seven hundred Jews murdered, A. D. 1262.

Edward I. seizes their property, A. D. 1290, and expels them.

In the third year of Edward I. a law passed the Commons concerning Judaism, which seemed to promise them some security. Nevertheless, in the year 1290, this monarch seized on all their real estates, and banished the whole of them from the kingdom. From 15,000 to 16,000 Jews were thus ruined, and then expelled. They left behind them several valuable libraries, particularly at Stamford and Oxford. The latter being sold among the students, most of the Hebrew books were bought by the famous Roger Bacon, who, in a short note written in one of them, declares they were of great service to him in his studies. The expulsion of the Jews at this time was so complete, that no farther traces of them in England occur till long after the Reformation.

Cromwell restores them.

Oliver Cromwell made the first attempt to restore to England the industry and wealth of the Jews: the intercourse between them was managed by means of one Henry Martin, who persuaded a deputation from the Jews at Amsterdam to wait upon the English ambassador there: from him they obtained permission to send a public envoy with proposals to London. Manasseh Ben Israel, who stiled himself a divine and doctor of physic, but who was in reality a printer and bookseller, was selected for this embassy, of which he published a particular account. On his arrival in England, he presented an address to Cromwell, recognising his authority, and soliciting his protection. On the 4th of December 1655, the Protector summoned a convention, consisting of two lawyers, seven citizens, and 14 noted preachers, to consult upon this request of the Jews; but he found so much prejudice and opposition, that, after a conference of four days, he dissolved the meeting. While this affair was pending, a Rabbi propagated the opinion that Cromwell was the expected Messiah. About this time a few appear to have settled in London, since, in the year 1663, their register of births contained twelve names; and during the whole reign of Charles II. who introduced the sale of patents of denization, their numbers increased. In 1684, James II. remitted the alien duty upon all goods exported in favour of the Jews. This privilege was opposed by the English merchants, petitions from the Hamburgh company, from the Eastland company, and from 57 of the leading merchants of the city, being presented against it. After the Revolution, this privilege was taken away from the Jews. In the first year of Queen Anne, a statute was passed to encourage the conversion of young Jews, by emancipating such converts from all dependance upon their parents; and in the 6th year of George II. it was proposed that the Lord Mayor and Court of Aldermen of London, should apply to Parliament for the suppression of Jew brokers; no public proceeding, however, ensued.

Numbers increase under Charles II.

Public proceedings respecting them, James II. William III. and 6th of George II.

Bill for naturalizing them, 1753.

Arguments in support of it.

In the 7th year of James I. an act was passed preventing all persons from being naturalized, unless they first received the sacrament of the Lord's supper, according to the rites of the church of England. This act effectually excluded the Jews from being naturalized. In the year 1753, a bill was brought into the House of Lords, and passed there without opposition, which provided that all persons professing the Jewish religion, who had resided in Great Britain or Ireland for three years, might be naturalized without receiving the sacrament of the Lord's supper. On the 16th of April this bill was sent down to the House of Commons, and, on its second reading, a motion was made for its being committed. The bill was supported by the petitions of a few merchants, chiefly dissenters: In behalf of it, it

Against it.

was argued, that it would increase the numbers and wealth of the people; that a great portion of the funds belonging to foreign Jews, it would be highly politic to induce them to follow their property; that, connected as the Jews were with the great bankers and monied interests of Europe, their residence in England would, in future wars, give the nation a great command of capital, and facilitate loans; that, even their prejudices as a sect would operate in our favour, and occasion our manufactures to be dispersed among the Jew-shopkeepers in Europe, who now had recourse to the Jew merchants of Holland and other tolerant countries; and lastly, that Poland had never risen to so high a pitch of prosperity, as when her policy was most liberal to the Jews; and that the sect itself had always abandoned its offensive prejudices in proportion to its good usage. On the other side it was urged, that by naturalizing the Jews, we should import vagrants and cheats to burden our rates, and supplant the industry of our labouring classes; that the rites of Jews would always prevent them from incorporating with the nation, or becoming any real addition to its intrinsic strength; while their early marriages and frequent divorces would occasion such a rapid increase of their numbers, that in the end they might become troublesome or even dangerous; that Jewish nationality would intrigue all the trade into their own hand; that they were enemies upon principle to all Christians; and that it was endeavouring to oppose the plans, and to frustrate the prophecies of the Almighty, to gather together a sect of which the Bible foretold the dispersion.

Petitions against it.

The lord mayor, aldermen, and livery of London, first presented a petition to parliament against the proposed naturalization, in which they expressed their apprehension that the bill, if passed into a law, would tend greatly to the dishonour of the Christian religion, and endanger the constitution. Alarm and prejudice spread rapidly and powerfully; a zeal, the most furious, vociferated in the pulpits and the corporations against the bill; and by the next sessions of parliament, instructions were sent to almost all the members to solicit a repeal of it; the minister yielded, and the bill was repealed by an act which received the royal assent the same session.

Repealed.

Laws regarding them.

By the 10th of George III. cap. 10, whenever any Jew shall present himself to take the oath of abjuration, the words "upon the true faith of a Christian," shall be omitted out of the oath. In courts of justice, they are sworn according to their peculiar rites. If Jewish parents refuse to allow their Protestant children a suitable maintenance, the lord chancellor may make such order as he may think proper.

Society for converting them.

A few years since a society was formed in London for promoting Christianity among the Jews, and branches of the society have been established in different parts of the kingdom. They have published several reports; but the utility of this society has been questioned, and it has been alleged, we hope without reason, that they have not been sufficiently attentive to the investigation of the character and probable motives of their converts.

Jews in France.

Our limits will not permit us to dwell long on the history or present state of the Jews in other countries; nor are we in possession of materials sufficient to enable us to enter into detail on these points. In France, the prejudices of Voltaire against the Jewish religion, for a long time prevented the philosophic sect in that country from extending their liberal ideas of toleration towards the Jews. In 1788, however, the academy at Metz proposed as a prize question, "Are there means of rendering the Jews in France usefuller and happier?" A Polish Jew, a counsellor of Nancy, and the celebrated Abbé Gregoire, shared the prize. The work of the Abbé on the moral, physical, and political regeneration of the Jews, is an admirable performance. In the constituent assembly, Mirabeau, Clermont, Tourere, and Rabaud, advocated their cause. The attention of the French government, however, does not seem to have been directed towards them till the year 1806, when Bonaparte issued a decree regarding them, in which he appointed an assembly of deputies from them at Paris in the month of July: when they met, they were attended by commissioners on the part of Bonaparte. After assurances of liberty and protection on the one hand, and of gratitude and obedience on the other, it was agreed that a grand Sanhedrim should be opened at Paris, at which should be preserved as much as possible the ancient Jewish forms and usages. This was announced to the Jews in France and Italy, in an address, which advised them to choose men known for their wisdom, in order to give to the Sanhedrim a proper degree of weight and consideration. The Sanhedrim assembled on the 9th of February 1807: they drew up 27 articles for the re-organization of the Mosaic worship; and passed several regulations on the subjects of divorce, polygamy, marriage, moral, civil, and political relations; useful professions, loans among themselves, and loans between Israelites, and those who are not Israelites. At their second meeting in March, a law for the condemnation of usury was passed. Bonaparte soon found, however, that he was not likely to accomplish his object of constraining his Jewish subjects to assist in the cultivation of the land, and in furnishing their quota of conscripts. In March 1808, he issued another decree respecting them, in which he calls upon them to follow the pursuits of honest industry, and to purchase landed property. This decree also annuls all obligations for loans made by Jews to minors, without the sanction of their guardians; to married women without the consent of their husbands; or to military men without the authority of their officers. There were also severe regulations respecting usury. At this period, the following return was made to Bonaparte of the number of Jews in all the different parts of the habitable globe, viz. in the Turkish empire, 1,000,000; in Persia, China, and India, on the east and west of the Ganges, 300,000; and in the west of Europe, Africa, and America, 1,700,000, making an aggregate population of 3,000,000. It would appear, however, from subsequent enquiries on this subject, that this number is very far below the truth. Indeed, in Poland alone, recent and well-informed travellers reckon that there are 2,000,000 Jews. The Prince Primate of Frankfort, following the example of Bonaparte, put an end to every humiliating distinction between the Jewish and Christian inhabitants of that city. Since the overthrow of Bonaparte, however, the inhabitants of Frankfort are said to have displayed great illiberality and intolerance against the Jews: and, indeed, this feeling has manifested itself generally throughout Germany. In this part of Europe, the popular prejudice against Judaism was attacked some years ago by Lessing in his plays of Nathan the Wise and the Monk of Lebanon; and, at the same time, Moses Mendelsolm published an excellent defence of general toleration, under the title of *Jerusalem.* C. W. Dohm, a Prussian, in the year 1781, published in German, *Re-*

In Germany.

Jews in Holland.

In Italy.

In Spain.

marks on the means of improving the civil condition of the Jews, which called forth several pamphlets on the same topic, of which the best were those of Schlotzer and Michaelis. In Holland, the condition of the Jews has long been favourable. In Italy, the first attempts were made to prepare the minds of the people for their toleration. Simone Lazzarato, of Venice, is mentioned as a pleader in their cause; the friends of the Socini, also, were thought to entertain sentiments favourable to them; but the interference of the inquisition in 1546, to suppress the club of Vicenza, proved prejudicial to the Jews, in depriving them of several of their most zealous advocates or apologists. In Spain, they obtained a footing after the Mahomedan conquest of that country, but they were driven out of it by the decrees of Ferdinand and Isabella. Mr Semple, in his second Journey in Spain, relates, that the Jews of Barbary, Smyrna, and Constantinople, generally speak corrupted Spanish, which he considers as a clear proof of the amazing numbers of that people that must have been driven out of Spain, and scattered all over the coasts of the Mediterranean. The laws, both of Spain and Portugal, are still most cruel against them, though they are not now often strictly enforced.

In Poland.

The Jews have long been very numerous and very favourably treated in Poland: it is said that they owe their privileges to Esther, a fair Jewess, the favourite mistress of Cassimir the Great; but it is probable that this monarch protected and encouraged them in his dominions, rather because in his time, (A. D. 1370), they were the richest and most commercial individuals in Europe. They still carry on the principal retail trade in all parts of Poland and Lithuania: a poll-tax is levied upon them.

In Asia and Africa.

Though it was not till after the Mahomedan conquest that the Jews obtained a "resting place for their feet" in Asia and southern Europe, yet in most of the Mahomedan states at the present day, they are treated with great cruelty and indignity. Mr Semple says, that the insults to which Christians are exposed in the states of Barbary, are nothing when compared with those which the Jews must hourly suffer. The Jews have larger settlements, and more permanent abodes in India, than they have any where in Europe. In Barbary, there are several thousand Jews, who do not refuse to communicate with the Mussulmans, or to bear arms. Cashmere also contains a large colony, supposed by Bernier to have settled there during the Babylonish captivity.

Traditions, customs, &c.

III. The Jewish history is generally divided into two periods: the first reaching from Abraham to Christ; the other from Christ to the present time; and the Jews of these two periods have been respectively distinguished as ancient and modern. The same distinction ought to be made with regard to Judaism, or the opinions, traditions, rites and ceremonies, of the Jews. Ancient Judaism may be defined as the system of doctrines and rites prescribed in the Old Testament; these were retained in their most essential points, though much corrupted, till the time of Christ: modern Judaism comprehends the opinions, traditions, rites and ceremonies, which began to be received before the destruction of the second temple, were afterwards systematized and embodied in the Cabalistic and Talmudic writings; and have been followed and professed by the great body of the Jewish nation ever since. Ancient Judaism is fully detailed in those parts of the Old Testament which treat of the law of Moses; in the remainder of this article, we propose to confine ourselves to a brief account of the most important parts of modern Judaism.

Their division of the Bible.

Targums.

The Jews divide the books of the Old Testament into three classes: the law, the prophets, and the hagiographa, or holy writings. They have counted not only the large and small sections, the verses and the words, but even the letters in some of the books; and they have likewise reckoned which is the middle letter of the Pentateuch, which is the middle clause of each book, and how often each letter of the alphabet occurs in the Hebrew scriptures. Besides the scriptures, the Jews pay great attention to the Targums, or Chaldee paraphrases of them: it seems probable that these were written either during the Babylonish captivity, or immediately afterwards, when the Jews had forgotten their own language, and acquired the Chaldee of the Targums, at present received by the Jews; the most ancient are that of Onkelos on the Law, and that of Jonathan Ben Uzliel on the Prophets: the former is supposed to be of greater antiquity than the latter, and it approaches in simplicity and purity of style to the Chaldee of Daniel and Esra. The Targum on the prophets is believed to have been written before the birth of Christ, and though inferior in respect of style to the Targum of Onkelos, is much superior to any other Targum.

Talmud.

The Jews also regard, with great veneration, what is called the Talmud. This work consists of two parts; the Mishna, which signifies a second law; and the Gemara, which means either a supplement or a commentary. The Jews suppose that God first dictated the text of the law to Moses, which he commanded to be put in writing, and which exists in the Pentateuch, and then gave him an explication of every thing comprehended in it, which he ordered to be committed to memory. Hence the former is called the written, and the latter the oral law. These two laws were recited by Moses to Aaron four times, to his sons three times, to the seventy elders twice, and to the rest of the people once; after this the repetition was renewed by Aaron, his two sons, and the seventy elders. The last month of Moses' life was spent, according to the Jews, in repeating and explaining the law to the people, and especially to Joshua his successor. A prophet might suspend any law, or authorise the violation of any precept, except those against idolatry. If there was any difference of opinion respecting the meaning of any law or precept, it was determined by the majority. When Joshua died, all the interpretations he had received from Moses, as well as those made in his time, were transmitted to the elders; these conveyed them to the prophets, and by one prophet they were delivered to another. This law was only oral, till the days of Rabbi Jehuda, who perceiving that the students of the law were gradually decreasing, and that the Jews were dispersed over the face of the earth, collected all the traditions, arranged them under distinct heads, and formed them into a methodical code of traditional law; thus the Mishna was formed. It is written in a concise style, chiefly in the form of aphorisms, which admit of a variety of interpretations. On this account, a gemara or commentary was written by a president of a school in Palestine, which, together with the mishna, forms the Jerusalem Talmud. The Jews in Chaldea, however, not being satisfied with this gemara, one of their Rabbis compiled another, which, together with the mishna, forms the Babylonian Talmud.

Cabala.

One of the principal branches of modern Judaism, is the Cabala, the study of which is regarded as the sublimest of all sciences. By the Cabala, the Jews mean those mystical interpretations of the scripture, and metaphysical speculations concerning the Deity, angels, &c. which they regard as having been handed down by a secret tradition from the earliest ages. The Cabala is of two kinds, theoretical and practical; the former relates to subjects only adapted to speculation; the latter is, in fact, a system of magic drawn from a mystical interpretation of the Scriptures. The Jews believe that Abraham, Moses, Solomon, &c. were adepts in this kind of magic. It was much cultivated in the middle ages; but now the Jews have in a great measure discarded faith in the practical Cabala.

In the 11th century, the famous Rabbi Maimonides drew up a summary of the doctrines of Judaism, which every Jew is required to believe, on pain of excommunication in this world, and condemnation in the next.

Articles of faith.

This summary consists of 13 articles, which he calls foundations or roots of the faith. The articles are as follow:—1. That God is the creator and active supporter of all things. 2. That God is one, and eternally unchangeable. 3. That God is incorporeal, and cannot have any material properties. 4. That God must eternally exist. 5. That God alone is to be worshipped. 6. That whatever has been taught by the prophets is true. 7. That Moses is the head and father of all contemporary doctors, and of all those who lived before or shall live after him. 8. That the law was given by Moses. 9. That the law shall always exist, and never be altered. 10. That God knows all the thoughts and actions of men. 11. That God will reward the observance, and punish the breach of the laws. 12. That the Messiah is to come, though he tarry a long time. 13. That there shall be a resurrection of the dead when God shall think fit.

Customs respecting child-birth.

Before the delivery of a Jewess, her husband, or some friend, describes with chalk a circle on each of the walls round the bed, and on the outside and inside of the door; he also inscribes on these, in Hebrew characters, the words, Adam, Chara, Chuts, Lilith; *i. e.* Adam, Eve, rejoice; Lilith signifying a wish, that if the child be a boy he may be like Adam, and blessed with a wife like Eve; but if a girl, that she may not, like Lilith, who, according to Jewish tradition, having been formed before Eve out of the ground, on that account deemed herself equal to Adam, and refused to be obedient to him. Lilith, also, is supposed to have the power of weakening and destroying young infants, and therefore the names of three angels are written on the inside of the chamber in which the pregnant woman lies. A Christian midwife must not be employed except in cases of most clear and urgent necessity, and then she must be surrounded and watched by several Jewesses. In order to accelerate the birth, a rabbi recites the 20th, 38th, 92d, and 102d psalms. On the evening of the Sabbath after delivery, if a boy is born, a feast is held called Jeshua Haben, or the safety of the son.

Circumcision.

Preparations are next made for circumcision. The guests must be at least ten in number, and must all have passed their 13th year. No woman or Christian is allowed to circumcise, except in cases of necessity. Where the latter performs the operation, some of the blood must be drawn afresh from the part by an Israelite. The regular circumcisers are distinguished by their very long and sharp nails; they are taught their business by operating on the sons of poor Jews, whose consent is obtained for money. Besides the circumciser, a person named Baal Berith, or the master of the covenant, must assist. The operation ought not to take place before the eighth, or later than the twelfth day after the birth. Two chairs are provided, one for the circumciser and the other for Elijah, who is supposed to be present. As soon as the circumciser and his attendant have entered the room, some boys make their appearance bearing twelve wax tapers, bowls of wine, a knife, a plate of sand, and a platter with olive oil, in which the linen to be applied to the wound is steeped. The infant must be bathed before the ceremony. He is brought to the door by a woman, who is not allowed to enter the room. If a child die uncircumcised, he is circumcised in the burial ground, that the reproach of uncircumcision may be taken away. No prayers are said on this occasion, but a name is given him, that, at the resurrection, when every one will be called by his name, his parents may recognise him. The birth of a girl is attended with little feasting. The rabbis have abolished the distinction made by the Mosaic law between the period of the purification of a woman after the birth of a son and a daughter. They have also altered the law respecting the mode of redemption of the first born, if a son.

Redemption of a son.

According to them, the child cannot be redeemed before the thirtieth day, nor after the thirty-first. On that day the priest asks the father, whether he would prefer his child, or the five shekels required for his redemption? to which the father replies, that he prefers his son, and that he wishes the priest to accept the money. The priest cannot accept less; but he may return what he accepts. If the father dies before the thirty-first day, the mother is not bound to redeem the child; but a piece of parchment is suspended on the child's neck, with an inscription, that he is a son not redeemed, to teach him, that he must redeem himself.

Education of females.

The education of the female children of the Jews is very much neglected. They are seldom taught more than to pronounce the words of a Hebrew prayer-book, without understanding the meaning of a single sentence.

Of males.

The sons are taught to read the law, the mishna, the gemara, and the prayer-book. Very few of them learn the Hebrew grammatically. At the age of 13 years and one day, a Jewish youth receives the appellation of Bar Mitsrah, a son of the commandment, and is required to observe the 613 precepts, which, according to the rabbis, comprehend the whole of the law. From this time he is deemed liable to punishment if he transgresses them; whereas the sins he commits before this age are ascribed to his father, who is liable to the punishment denounced against them. At this age the father, in the presence of several Jews, declares, that he is no longer chargeable for the sins of his son. Jewish girls are accounted of full age at 12 years and a day old.

Marriages.

Marriage is reckoned the indispensible duty of every Jew. Men who live in celibacy long after eighteen are considered by the rabbis as living in sin. Polygamy is sanctioned by the Talmud, but is not practised by the European Jews. The betrothing sometimes takes place six months or a year before the marriage. Ten men at least must be present at the marriage, otherwise it is null. A velvet canopy is brought into the room where the ceremony is to take place, and extended on four poles. Under this canopy the bride, having her face covered with a veil, is led by two women, and the bridegroom by two men; these are always their parents, or near relations. After a short prayer, the bride and bridegroom drink of the wine which is offered them by the rabbi. A ring is used, as at Christian marriages. The marriage contract is next read; and, as soon as the reading is ended, the priest takes another glass of wine, and repeats seven benedictions; then the married couple drink the wine; after which the empty glass is laid on the floor, and the bridegroom stamping on it breaks it to pieces, indicating by this the frailty of life. The company next shout, “Good luck to you!” The ceremony is concluded by a contribution for the poor in the land of Canaan, and a nuptial feast.

Divorces.

A Jew is at liberty to divorce his wife at any time, or for any cause; but, in order to counteract the consequences of this liberty, the synagogue has ordered a great many formalities to be observed, which allow time for the parties to become cool, and to reconsider the matter. When the divorce takes place, the parties are not allowed to marry again, nor to be together by themselves: if the woman has been divorced for adultery, she cannot marry her paramour. A man at a distance from his wife, may send her a bill of divorce by a messenger, which is legal, provided the messenger is specially appointed—heard the husband order the notary to write the bill—saw it written and signed—received it from the husband in the presence of two subscribing witnesses, with a special and formal commission, and provided he delivers it to the woman in the presence of two witnesses, with a prescribed declaration of its nature. A girl betrothed under ten years of age is entitled to a divorce any time before she arrives at the age of twelve years and a day, simply by declaring before two witnesses, who write out her declaration, that she will not marry the man; this is called a divorcement of dislike.

Singular change of names.

Rites at deaths, and burials.

In reading the Jewish prayers for the sick, it is customary, in cases of great and imminent danger, to change the name of the sick person, under the belief that thus the sentence of death which may have been issued against him in heaven may be averted or evaded. There is a particular form in their liturgy for changing the name, in which it is said to be done with the knowledge of God, and the approbation of the celestial tribunal; and that his change of name may annul all hard decrees, and reverse the sentence which may have passed against him. In this prayer, he is represented as another man, an infant just born, &c. When a Jew dies, all the water in the same and adjoining houses is instantly thrown away, and no priest must, on any account, remain in any of these houses till the body is removed. Immediately on his decease, the body is stripped and laid on the floor with clean straw under it, and watched by a Jew till the ceremony of cleansing it with warm water is performed. During this ceremony great care must be taken that no water enters the mouth of the corpse. Near it are placed a lighted taper, a bason of water, and a clean towel, that the soul may cleanse itself from the defilements it contracted in this world. For this purpose it is supposed to return to the place every night for a month, during which period the things are kept in the room, and the water is changed every night. In cases where the relations of the deceased are too poor to defray the expence of this ceremony, a subscription is made by the richer Jews; and a few years ago a society was established in London for this purpose—so very sacred and imperative is this ceremony esteemed. The Jews do not make use of close coffins, but only four plain boards loosely joined together. This is done in order that the worms may the sooner destroy the body. The talleh, or square garment with fringes, is put over the sepulchral garment. At the place of interment, the coffin is opened, and some earth, said to have been brought from Jerusalem, is placed under the head in a small bag, or strewed about the body. The relations and friends of the deceased then take hold, one after the other, of his great toes, imploring him to pardon all their offences against him, and not to report evil against them in the other world. The nearest relations rend their garments. When the coffin is placed in the grave, each of the relations throws some earth on it. As soon as the grave is filled, all the attendants run away lest they should hear the knock of the angel, who is supposed to come and knock on the coffin, and to ask the deceased if he can repeat the passage in scripture which has an allusion to his name: if he is not able to repeat it, the angel beats him with a hot iron till he breaks his bones. When the relations return from the funeral, they all sit down on the floor, and eat a small portion of hard boiled eggs, salt, and bread, in order to break the fast which they are supposed to have kept from the moment of the decease of their relation. Morning and evening, ten Jews who have passed the age of thirteen repeat prayers for the dead; and at the close of these prayers, the nearest male relatives repeat the Kodesh, a prayer which is supposed to deliver the deceased from hell. The Jews believe in a resurrection, but the rabbis say it will take place in the land of Canaan, and that Israelites buried in other countries will be rolled thither through subterranean caverns; hence Jews in neighbouring countries, if rich, are removed into Canaan before they die. On the decease of a brother, sister, wife, daughter, or son, the upper garment is cut on the right side, and then rent about a hand-breadth in length; but on the death of a father or mother, the rent is made on the left side in all the garments. The mourning continues seven days, during which no business is to be transacted, nor is the house to be left; but the mourners are to sit on the ground without shoes, and to give free access to every visitant: they must not shave their beards, cut their nails, or wash themselves for 30 days.

Garments.

There are very particular rules laid down by the rabbis respecting the materials, form, and colours of the garments to be worn by the Jews; but in general they conform to the mode of dress in the country where they reside. It is, however, deemed unlawful to wear any garment made of linen and woollen woven together, or made with either of these and sewed with the other. Every male is required to have a quadrangular garment, called talleh. It consists of two quadrangular pieces of woollen or silk joined together at the upper edge by two fillets. These rest on the shoulders, and the pieces hang down, one on the back, and the other over the breast. This is constantly worn as an inner garment. From each of the corners hangs a fringe, consisting of eight threads, and tied with five knots. The sanctity of this garment is supposed to depend upon these fringes, The threads composing them must be of wool that has been shorn, not pulled, and spun by a Jewess for the express purpose. There are also minute and very particular regulations regarding the colour and the folding of the threads. The talleh is not required to be worn at night, nor is the wearing of it obligatory on women, servants, or young children. It is never to be sold or pledged to a Christian. Other appendages of Jewish devotion are the phylacteries, one for the head, and one for the arm. The former is made of skin or leather stretched on a block, and sewed so as to form a leathern box, divided into four compartments, having impressed on one side of it the letter Shin, and on the other a character resembling that letter, only with four points instead of three. In the compartments are inclosed four passages of the law, written on parchment, which is bound round with hair pulled from the tail of a cow, and well washed. The strap which fastens the phylactery to the head ought to be black on the outside, and any colour except red on the inside. It is fastened in such a manner, that the little box including the parchments rests on the forehead below the hair, so that the divine precepts may be fixed in the brain. The phylactery for the arm is nearly similar, except that it has only one cavity, and is without the impression of the letter Shin. It is fastened to the naked skin, on the inner part of the left arm, so as to be near the heart. It would be tiresome to enumerate the directions for tying on these phylacteries, which are excessively minute and multifarious. Besides phylacteries, there are schedules for door-posts, which are generally placed on the right hand of the entrance, and touched or kissed by such of the Jews as wish to be deemed very devout.

Synagogues.

No synagogue can be instituted except there be at least ten men who have passed the age of thirteen. The highest ground is chosen, and no Jew is permitted to build a house of superior or even equal height. In prayer, their faces are always turned towards the land of Canaan; the door of the synagogue, therefore, is always placed at the opposite point of the compass. A closet or chest called the Ark, in which the book of the law is deposited, is opposite to the entrance into the synagogue. Every copy of the pentateuch must be in manuscript. The rabbis have laid down rules for transcribing it, which must on no account be omitted or infringed. The ink employed is to be made of prescribed ingredients. The book itself is to be in the form of a roll. Near the middle of the synagogue is a desk or altar where the law is read, and sermons delivered. No seats are admitted between the altar and the ark. The women are not allowed to sit with the men, and they are even screened from their notice by a wooden lattice. In each synagogue there is a reader or chanter, clerks for the management of pecuniary matters, besides inferior attendants. The general business of the congregation is superintended by wardens or elders. The privilege of folding and unfolding the law, and of performing other public services, is accounted a high honour, and, as such, is put up to public auction. The money arising from these sales is paid into the general stock of the synagogue.

In every country there is a chief, or presiding rabbi, who exercises not only a spiritual, but also a civil, jurisdiction: his authority is kept up by ecclesiastical censures, excommunications, &c. The title of rabbi is little more than an honorary distinction, and is easily obtained by any individual well versed in the Talmud.

Religion, ceremonies, prayers, &c.

The Jewish religion is, perhaps, more a religion of minute and trifling rites and ceremonies, than even the Catholic religion. The minutest circumstances in dressing and undressing, washing and wiping the face and hands, and other necessary actions of common and daily life, are enjoined by the rabbis to be performed exactly according to the prescribed regulations. Their prayers also are numerous, and some of them relate to the most trifling circumstances. Those esteemed the most solemn and important are called *Shemoneh Esreh*, or the Eighteen prayers, though they actually consist of nineteen, the last having been added against heretics and apostates. They are enjoined to be said by all Jews above the age of thirteen, wherever they may be, three times a-day. The members of the synagogue are required to repeat at least a hundred benedictions every day. A son who survives his father is enjoined to attend the nocturnal service in the synagogue every evening for a year, and to repeat the Kodesh, in order that his father may be delivered from hell. This service may be suspended by any person going up to the desk and closing the book. This is not unfrequently done in case of quarrels; and the prayers cannot be renewed till a reconciliation takes place.

Sabbath.

Nothing is to be undertaken on a Friday which cannot be finished before the evening. In the afternoon they wash and clean themselves, trim their hair, and pare their nails. They begin with the left hand, but think it wrong to cut the nails on two adjoining fingers in succession. Even the parings are directed by the Talmud to be disposed of in a particular manner; for it says, "he that throws them on the ground is an impious man; he that buries them is a just man; he that throws them into the fire is a pious and perfect man." Every Jew, of whatever rank, must assist in the preparation for the Sabbath. Two loaves, baked on the Friday, are set on a table. This is done in memory of the manna, of which a double portion fell on the sixth day of the week. The table remains spread all the Sabbath. Before the sun is set, the candles are to be lighted; one at least with seven wicks, in allusion to the number of days in a week, is to be lighted in each house. The Talmudical directions respecting the wicks and oil form part of the Sabbath evening service; they are most ridiculously and childishly minute. The lesson appointed for the Sabbath is divided into seven parts, and read to seven persons at the altar. The first called up to hear it, is a descendant of Aaron, the second of Levi, the third an Israelite of any tribe; the same order is then repeated; the seventh may be of any tribe. The portion read from the law is followed by a portion from the prophets. There are three services, morning, afternoon, and evening. On their return from the last, a wax candle, or a lamp with two wicks, is lighted, and held by a child. The master then takes a glass of wine in his right hand, and a box of spices in his left. After a prayer, a little of the wine is spilled on the floor; and the wine being taken in the left, and the spices in the right hand, after another prayer, he and all the family smell to the spices, and taste the wine. This ceremony is called *Habdala*, or the separation, because it separates the Sabbath from other days. The works forbidden on the Sabbath, according to the rabbis, may be reduced under thirty-nine general heads; of which writing, blotting out, ruling paper, kindling a fire or quenching it, form some. Other forbidden actions are brought under these heads by a very forced analogy. Thus, curdling milk is included under the forbidden head of building, because a whole is formed by the composition of different bodies. Filling ditches is deemed unlawful, and therefore some rabbis have forbidden the sweeping of a room on the Sabbath, lest any furrow or chink in the floor should be filled by the operation. Walking over new ploughed ground is also forbidden, lest a hole should thus be filled up. A tailor must not go out of doors with a needle stuck in any of his clothes. The use of stilts is prohibited, because, though the stilts seem to carry the man, yet in fact the man carries the stilts, and to bear a burden on the Sabbath is unlawful. Dirt on the coat, &c. may be scraped off with the nails while it is moist, but not if it is dry, because thus it would raise some dust, and that would resemble grinding or breaking to pieces.

Chronology. The vulgar Jewish chronology reckons only 1948 years to the birth of Abraham, and in several other particulars it is at variance with the Bible. The modern Jews follow the practice of their ancestors, while in Egypt, of commencing the year at the autumnal equinox. The present Jewish calendar was settled by Rabbi Hittel, about the middle of the 4th century of the Christian era, and is constructed with great ingenuity and astronomical exactness, not equalled by Christians till the improvement of the Julian calendar by Pope Gregory.

Festivals. Of the festivals of the Jews we can mention only a few, and those merely in a cursory manner. The principal are those of the new moon, of the Passover, of Pentecost, of the new year, the fast of atonement, and the feast of tabernacles. That the festival of the new moon might be celebrated as nearly as possible on the day of the moon's conjunction with the sun, most of the months contain alternately twenty-nine and thirty days; and the feast of the new moon is held on the first, or on the first and second days of the month; the women are not allowed to work, the men may. Good eating and drinking particularly distinguish this festival. The feast of the Passover commences on the 15th day of the month Nisan, and continues among Jews who live in or near Jerusalem seven days, and elsewhere eight days. The Sabbath preceding is called the Great Sabbath, and is kept with most scrupulous strictness. The mode and materials for making the unleavened cakes for the Passover, are most minutely described by the rabbis, as well as all the ceremonies of this feast. It is customary for every Jew to honour it by an exhibition of the most sumptuous furniture he can afford. The table for the feast is covered with a clean linen cloth, on which are placed several dishes; on one is the shank bone of a shoulder of lamb or kid, and an egg; on another, three cakes, wrapped in two napkins; on a third, some lettuce, parsley, celery, or other herbs; these are their bitter herbs. Near the sallad is a cruet of vinegar, and some salt and water. There is also a dish, representing the bricks which their forefathers were required to make in Egypt: this is composed of apples, almonds, nuts, and figs, formed into a paste, dressed in wine and cinnamon. The first two days, and the last two, are kept with particular solemnity and strictness. Contracts of marriage may be made, but no marriage is to be solemnized during this festival. The feast of Pentecost, on the 6th day of the month Sivan, continues two days, and is kept with the same strictness as the first two days of the Passover. It is a received opinion of the Jews, that the world was created on the day of their new year; and they therefore celebrate the festival of the new year by a discontinuance of all labour, and by repeated services in the synagogue. The fast of atonement is on the 10th day of Tisri; the first ten days of the month are called days of penitence, during which the Jews believe that God examines the actions of mankind, but he defers passing sentence till the tenth. On the eve of the fast, a ceremony, evidently designed as a substitute for their ancient sacrifices, is performed; this consists in killing a cock, with great formality. The cocks must on no account be red; white is the preferable colour. Before the fast begins, they endeavour to settle all their disputes. In the afternoon they make a hearty meal to prepare for the fast, which is of the most rigid kind. The feast of tabernacles commences on the 15th of Tisri, and is kept nine days. Every Jew who has a court or garden is required to erect a tabernacle on this occasion, respecting the materials and erection of which the rabbis have given special directions. The eighth and ninth are high days, particularly the last, which is called the day of the rejoicing of the land.

Food. The Jews are not permitted to taste the flesh of any four-footed animals, except those which both chew the cud and part the hoof; nor any fish except such as have both scales and fins; they are not to eat the blood of any beast or bird. Cattle for their use must be slaughtered by a Jew, duly qualified, and especially appointed for that purpose. If the carcase has the least blemish, it cannot be eaten; if it is perfectly sound, he affixes to it a leaden seal, with the word *casher*, right, and the day of the week. If there be no Jew butcher, a Jew appointed by the synagogue is stationed at the Christian butcher's to superintend the cutting up of the carcase, and to affix the seal. The hind quarters are not to be eaten unless the sinew of the thigh is taken out. A cow and her calf, an ewe and her lamb, a she goat and her kid, must not be killed in the same day. The knife used for slaughter must be very sharp and free from notches. Meat and butter must not be eaten together, on account of the law, "not to seethe a kid in his mother's milk." For this reason, also, they make their cheese without rennet. No knife, fork, spoon, or culinary vessel, used for meat, is to be used for milk.

Caraites. Such are the opinions, traditions, rites and ceremonies, of the great majority of the modern Jews; but besides these, there is a small sect denominated Caraites, that is textualists—persons attached to the text of the Scriptures. They reside chiefly in the Crimea, Lithuania, and Persia; and at Damascus, Constantinople, and Cairo; their whole number is very inconsiderable. They agree with other Jews in denying the advent of the Messiah. The principal difference between them consists in their adherence to the letter of the Scripture, and in their rejection of all paraphrases and interpretations of the rabbis. They also differ from the rabbis in various particulars respecting the feasts of the Passover, Pentecost, and Tabernacles. They observe the Sabbath with far greater strictness; they extend the degrees of affinity within which marriage is prohibited, but they are more strict in matters of divorce.

IGNATIUS LOYOLA. See LOYOLA.

IGNIS FATUUS, commonly called *Will i'the Wisp*, or *Jack and the Lanthorn*, is a meteor which is commonly seen in dark nights, in marshy grounds and other damp places. A full account of it will be given under the article METEORS.

IGUANA. See HERPETOLOGY.

JHANSU-JEUNG. See THIBET.

JIDDA, JEDDA, JODDA, ZITTA, or DSCHEDA, is a small trading town of Arabia Felix, situated in the district of Tahamah, about 40 miles distant from Mecca, north latitude 20° 28′ 1″, and east longitude from

Greenwich 39° 16′ 45″. It is defended by a fort, and surrounded by a ruinous wall, built in the year 1514. Its harbour is very extensive, formed by numberless reefs of Madrapore, extending about four miles from the shore, and full of small islands and sunken rocks. The entrance is sufficiently dangerous, but the pilots are expert, steering safely by the eye alone, and easily perceiving the rocks below the smooth surface, especially when the sun is behind the vessel. Between these shoals and islands are deep channels, with a good bottom, where ships may lie at anchorage in six or twelve fathoms, and where the water is as smooth as glass, in the heaviest gales. The surrounding country is sandy, barren, and destitute of water, and the town is very ill supplied with provisions. A desert plain to the eastward is occupied by Bedouins, or country Arabs, who live in huts made of long bundles of bent grass, or spartum, and who supply the inhabitants of Jidda with milk and butter. The situation is as unwholesome as it is unproductive; and, besides several stagnant pools in the vicinity, the north-west wind which chiefly prevails, blowing along the direction of the gulf, brings a great dampness through the greater part of the year. The highest degree of the thermometer observed by Mr Bruce in July was 97°, and the lowest 78°. The barometer in June was between 26° 6′, and 25° 7′; wind north-west. The town of Jidda derives all its celebrity, and even its existence, from its vicinity to the city of Mecca, to which it is the nearest sea-port, and the great receptacle of the India trade, which arrives once a-year. The inhabitants of the place, indeed, derive little advantage from this rich traffic, which passes on to Mecca, and for which the payments return to the ships, without leaving much profit by the way to the townsmen. The influx of strangers, on the contrary, raises the price of provisions; and the native traders, after the market is over, which does not last above six weeks, retire to Yemen and the neighbouring countries, where every article of subsistence is found in abundance. Jidda, however, is also the great depot of all merchandize intended to be carried to Suez for the demands of Egypt; and great multitudes of the inhabitants find employment in landing and reshipping these goods, in providing warehouses for their safe deposit, and in acting as factors in receiving and disposing of them. The English traders, in 1777, made an attempt to carry their cargoes directly to Suez, without passing them through Jidda into native vessels; and this trade, which continued about three years, was encouraged by the Egyptian Beys, as the English merchants paid them twice as much impost as the Jidda importers. But the Sheriffe of Mecca, who draws the customs of the port of Jidda, procured an order from the Grand Seignior, that all vessels bound for Egypt should stop at Jidda, and pay duty there; and obliged the merchants, when once in his harbour, to unship their goods, and send them forward to Suez in other vessels. The Sultan secured a share of these profits, and regularly appointed a pasha, who resided in the citadel of Jidda, and divided the receipts of the custom-house with the Sheriffe's Vizier. During the convulsions of Egypt, and the insurrections of the Wachabees, the Sheriffe contrived to expel the representative of the Sultan, and to appropriate the whole duties to himself. His extortions, however, in the name of presents to himself and his servants, have caused a great diminution of the trade formerly carried on by the English with Jidda; and many of the richest merchants have retired from the place. The Sheriffe, made aware of his folly by the reduction of his revenues, has become more moderate in his demands. The duties recently proposed, amount to about eight per cent. and the presents to about half as much; but a merchant, when once in the harbour, from which he could scarcely escape without a native pilot, could never be secure against further demands. See Bruce's *Travels*, vol. ii.; Parson's *Travels*; and Valentia's *Travels*, vol. iii. (*q*)

ILANTZ, in the Rhetian language *Ilan* or *Ilon*, a town of Switzerland, in the territory of the Grisons, and the capital of the division of the Grey League. The town is situated in the widest part of the valley of the same name, at the foot of the mountain Mundaun, or Karlisberg. It is the first town that we meet with on the Rhine, and is the only town in the world where the Rhetian language is still spoken. It has two fauxbourgs, viz. that of St Nicholas, and that of Portasura. The bridge built over the Rhine is remarkable. The inhabitants profess the reformed religion. The women in the neighbourhood are very much subject to the Goitre necks.

The tribunal of the Grey League meets at Ilantz, Thousis, and Trons, in rotation; but it is at Ilantz that the archives of the League are preserved. A great fair for cattle is held at Ilantz. Excellent fish, about 22 pounds weight, are caught in the Rhine.

At Rouvis, above Ilantz, on the left bank of the Rhine, a mine of galæna, containing silver, has been wrought. The mineral is contained in nests in the gneiss. The mine of Rouvis, and one of yellow copper at Ober-Sax, have been wrought since the year 1806 by M. Demengha. In descending the valley of Ilantz, the rocks are composed of argillaceous schistus as far as Tamino. See Ebel's *Manuel d'une Voyageur en Suisse*, tom. iii. p. 227.
